## FEATURES

AD5301: buffered voltage output 8-bit DAC
AD5311: buffered voltage output 10-bit DAC
AD5321: buffered voltage output 12-bit DAC
6-lead SOT-23 and 8-lead MSOP packages
Micropower operation: $120 \mu \mathrm{~A}$ @ 3 V
2-wire ( $\mathbf{I}^{2} \mathbf{C}^{\ominus}$-compatible) serial interface
Data readback capability
2.5 V to 5.5 V power supply

Guaranteed monotonic by design over all codes
Power-down to 50 nA @ 3 V
Reference derived from power supply
Power-on reset to 0 V
On-chip rail-to-rail output buffer amplifier 3 power-down functions

## APPLICATIONS

Portable battery-powered instruments Digital gain and offset adjustment
Programmable voltage and current sources
Programmable attenuators

## GENERAL DESCRIPTION

The AD5301/AD5311/AD5321 ${ }^{1}$ are single 8-/10-/12-bit, buffered, voltage-output DACs that operate from a single 2.5 V to 5.5 V supply, consuming $120 \mu \mathrm{~A}$ at 3 V . The on-chip output amplifier allows rail-to-rail output swing with a slew rate of $0.7 \mathrm{~V} / \mu \mathrm{s}$. It uses a 2 -wire ( $\mathrm{I}^{2} \mathrm{C}$-compatible) serial interface that operates at clock rates up to 400 kHz . Multiple devices can share the same bus.
The reference for the DAC is derived from the power supply inputs and thus gives the widest dynamic output range. These parts incorporate a power-on reset circuit, which ensures that the DAC output powers up to 0 V and remains there until a valid write takes place. The parts contain a power-down feature that reduces the current consumption of the device to 50 nA at 3 V and provides software-selectable output loads while in power-down mode.
The low power consumption in normal operation makes these DACs ideally suited to portable battery-operated equipment. The power consumption is 0.75 mW at 5 V and 0.36 mW at 3 V , reducing to $1 \mu \mathrm{~W}$ in all power-down modes.
${ }^{1}$ Protected by U.S. Patent No. 5684481.

## AD5301/AD5311/AD5321

${ }^{1}$ Temperature range is as follows: B Version: $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$.
${ }^{2}$ See the Terminology section.
${ }^{3}$ DC specifications tested with the outputs unloaded.
${ }^{4}$ Linearity is tested using a reduced code range: AD5301 (Code 7 to 250); AD5311 (Code 28 to 1000); and AD5321 (Code 112 to 4000).
${ }^{5}$ Guaranteed by design and characterization, not production tested.
${ }^{6}$ Input filtering on both the SCL and SDA inputs suppress noise spikes that are less than 50 ns .

## AC CHARACTERISTICS ${ }^{1}$

$\mathrm{V}_{\mathrm{DD}}=2.5 \mathrm{~V}$ to $5.5 \mathrm{~V} ; \mathrm{R}_{\mathrm{L}}=2 \mathrm{k} \Omega$ to $\mathrm{GND} ; \mathrm{C}_{\mathrm{L}}=200 \mathrm{pF}$ to GND; all specifications $\mathrm{T}_{\mathrm{MIN}}$ to $\mathrm{T}_{\mathrm{MAX}}$, unless otherwise noted.
Table 2.

|  | B Version $^{2}$ |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |

## ABSOLUTE MAXIMUM RATINGS

$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted. ${ }^{1}$
Table 4.

| Parameter | Rating |
| :---: | :---: |
| $V_{\text {DD }}$ to GND | -0.3 V to +7 V |
| SCL, SDA to GND | -0.3 V to $\mathrm{V}_{\mathrm{DD}}+0.3 \mathrm{~V}$ |
| $\overline{\mathrm{PD}}, \mathrm{A} 1, \mathrm{~A} 0$ to GND | -0.3 V to $\mathrm{V} D+0.3 \mathrm{~V}$ |
| Vout to GND | -0.3 V to $\mathrm{V} D+0.3 \mathrm{~V}$ |
| Operating Temperature Range Industrial (B Version) | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Junction Temperature (T, max) | $150^{\circ} \mathrm{C}$ |
| SOT-23 Package Power Dissipation $\theta_{\mathrm{JA}}$ Thermal Impedance | $\begin{aligned} & \left(\mathrm{T}_{J}^{\max -}-\mathrm{T}_{\mathrm{A}}\right) / \theta_{\mathrm{JA}} \\ & 229.6^{\circ} \mathrm{C} / \mathrm{W} \end{aligned}$ |
| MSOP Package Power Dissipation $\theta_{\mathrm{JA}}$ Thermal Impedance | $\begin{aligned} & \left(\mathrm{T}_{J}^{\left.\max -\mathrm{T}_{\mathrm{A}}\right) / \theta_{\mathrm{JA}}}\right. \\ & 206^{\circ} \mathrm{C} / \mathrm{W} \end{aligned}$ |
| Lead Temperature Soldering | JEDEC Industry Standard J-STD-020 |

${ }^{1}$ Transient currents of up to 100 mA do not cause SCR latch-up.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 3. 8-Lead MSOP
(RM-8) Pin Configuration

Figure 4. 6-Lead SOT-23
(RJ-6) Pin Configuration

Table 5. Pin Function Descriptions

| MSOP Pin No. | SOT-23 <br> Pin No. | Mnemonic | Description |
| :---: | :---: | :---: | :---: |
| 1 | 6 | $V_{\text {DD }}$ | Power Supply Input. These parts can be operated from 2.5 V to 5.5 V and the supply should be decoupled with a $10 \mu \mathrm{~F}$ in parallel with a $0.1 \mu \mathrm{~F}$ capacitor to GND. |
| 2 | 5 | A0 | Address Input. Sets the least significant bit of the 7-bit slave address. |
| 3 | N/A | A1 | Address Input. Sets the second least significant bit of the 7-bit slave address. |
| 4 | 4 | $\mathrm{V}_{\text {out }}$ | Buffered Analog Output Voltage from the DAC. The output amplifier has rail-to-rail operation. |
| 5 | N/A | $\overline{P D}$ | Active Low Control Input. Acts as a hardware power-down option. This pin overrides any software power-down option. The DAC output goes three-state and the current consumption of the part drops to $50 \mathrm{nA} @ 3 \mathrm{~V}$ ( $200 \mathrm{nA} @ 5 \mathrm{~V}$ ). |
| 6 | 3 | SCL | Serial Clock Line. This is used in conjunction with the SDA line to clock data into the 16-bit input shift register. Clock rates of up to 400 kbps can be accommodated in the $I^{2} \mathrm{C}$-compatible interface. SCL may be CMOS/TTL driven. |
| 7 | 2 | SDA | Serial Data Line. This is used in conjunction with the SCL line to clock data into the 16-bit input shift register during the write cycle and to read back one or two bytes of data (one byte for the AD5301, two bytes for the AD5311/AD5321) during the read cycle. It is a bidirectional open-drain data line that should be pulled to the supply with an external pull-up resistor. If not used in readback mode, SDA may be CMOS/TTL driven. |
| 8 | 1 | GND | Ground Reference Point for All Circuitry on the Part. |

## AD5301/AD5311/AD5321

## TERMINOLOGY

## Relative Accuracy

For the DAC, relative accuracy or integral nonlinearity (INL) is a measure of the maximum deviation, in LSBs, from a straight line passing through the actual endpoints of the DAC transfer function. Typical INL vs. code plots can be seen in Figure 5 to Figure 7.

## Differential Nonlinearity (DNL)

DNL is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of $\pm 1$ LSB maximum ensures monotonicity. These DACs are guaranteed monotonic by design over all codes. Typical DNL vs. code plots can be seen in Figure 8 to Figure 10.

## Zero-Code Error

Zero-code error is a measure of the output error when zero code ( 0 x 00 ) is loaded to the DAC register. Ideally, the output should be 0 V . The zero-code error of the AD5301/AD5311/ AD5321 is always positive because the output of the DAC cannot go below 0 V , due to a combination of the offset errors in the DAC and output amplifier. It is expressed in millivolts, see Figure 12.

## Full-Scale Error (FSR)

Full-scale error is a measure of the output error when full scale is loaded to the DAC register. Ideally, the output should be $V_{D D}-1$ LSB. Full-scale error is expressed in percent of FSR. A plot can be seen in Figure 12.

## Gain Error

Gain error is a measure of the span error of the DAC. It is the deviation in slope of the actual DAC transfer characteristic from the ideal expressed as a percentage of the full-scale range.

## Zero-Code Error Drift

Zero-code error drift is a measure of the change in zero-code error with a change in temperature. It is expressed in $\mu \mathrm{V} /{ }^{\circ} \mathrm{C}$.

## Gain Error Drift

Gain error drift is a measure of the change in gain error with changes in temperature. It is expressed in (ppm of full-scale range) $/{ }^{\circ} \mathrm{C}$.

## Major Code Transition Glitch Energy

Major code transition glitch energy is the energy of the impulse injected into the analog output when the code in the DAC register changes state. It is normally specified as the area of the glitch in nV -s and is measured when the digital code is changed by 1 LSB at the major carry transition ( $011 \ldots 11$ to $100 \ldots 00$ or $100 \ldots 00$ to $011 \ldots$. 11).

## Digital Feedthrough

Digital feedthrough is a measure of the impulse injected into the analog output of the DAC from the digital input pins of the device, but is measured when the DAC is not being written to. It is specified in nV -s and is measured with a full-scale change on the digital input pins, that is, from all 0 s to all 1 s and vice versa.

## THEORY OF OPERATION

The AD5301/AD5311/AD5321 are single resistor-string DACs fabricated on a CMOS process with resolutions of 8/10/12 bits, respectively. Data is written via a 2 -wire serial interface. The devices operate from single supplies of 2.5 V to 5.5 V and the output buffer amplifiers provide rail-to-rail output swing with a slew rate of $0.7 \mathrm{~V} / \mu \mathrm{s}$. The power supply $\left(\mathrm{V}_{\mathrm{DD}}\right)$ acts as the reference to the DAC. The AD5301/AD5311/AD5321 have three programmable power-down modes, in which the DAC can be turned off completely with a high impedance output, or the output can be pulled low by an on-chip resistor (see the Power-Down Modes section).

## DIGITAL-TO-ANALOG

The architecture of the DAC channel consists of a resistor string DAC followed by an output buffer amplifier. The voltage at the $V_{D D}$ pin provides the reference voltage for the DAC. Figure 24 shows a block diagram of the DAC architecture. Since the input coding to the DAC is straight binary, the ideal output voltage is given by

$$
V_{\text {OUT }}=\frac{V_{D D} \times D}{2^{N}}
$$

where:
$N=$ DAC resolution
$D=$ decimal equivalent of the binary code that is loaded to the DAC register:

$$
\begin{aligned}
& 0-255 \text { for AD5301 (8 bits) } \\
& 0-1023 \text { for AD5311 (10 bits) } \\
& 0-4095 \text { for AD5321 (12 bits) }
\end{aligned}
$$

Figure 24. DAC Channel Architecture

## RESISTOR STRING

The resistor string section is shown in Figure 25. It is simply a string of resistors, each with a value of R. The digital code loaded to the DAC register determines at what node on the string the voltage is tapped off to be fed into the output amplifier. The voltage is tapped off by closing one of the switches connecting the string to the amplifier. Because it is a string of resistors, it is guaranteed monotonic over all codes.

## OUTPUT AMPLIFIER

The output buffer amplifier is capable of generating output voltages to within 1 mV from either rail, which gives an output range of 0.001 V to $\mathrm{V}_{\mathrm{DD}}-0.001 \mathrm{~V}$. It is capable of driving a load of $2 \mathrm{k} \Omega$ to GND and $\mathrm{V}_{\mathrm{DD}}$, in parallel with 500 pF to GND. The source and sink capabilities of the output amplifier can be seen in Figure 14.
The slew rate is $0.7 \mathrm{~V} / \mu \mathrm{s}$ with a half-scale settling time to $\pm 0.5$ LSB (at 8 bits) of $6 \mu$ s with the output unloaded.

## POWER-ON RESET

The AD5301/AD5311/AD5321 are provided with a power-on reset function, ensuring that they power up in a defined state.

The DAC register is filled with zeros and remains so until a valid write sequence is made to the device. This is particularly useful in applications where it is important to know the state of the DAC output while the device is powering up.

## AD5301/AD5311/AD5321

## SERIAL INTERFACE

## 2-WIRE SERIAL BUS

The AD5301/AD5311/AD5321 are controlled via an $\mathrm{I}^{2} \mathrm{C}$ compatible serial bus. The DACs are connected to this bus as slave devices (no clock is generated by the AD5301/AD5311/ AD5321 DACs).

The AD5301/AD5311/AD5321 has a 7 -bit slave address. In the case of the 6-lead device, the six MSBs are 000110 and the LSB is determined by the state of the A0 pin. In the case of the 8 -lead device, the five MSBs are 00011 and the two LSBs are determined by the state of the A0 and A1 pins. A1 and A0 allow the user to use up to four of these DACs on one bus.

The 2-wire serial bus protocol operates as follows:

1. The master initiates data transfer by establishing a start condition, which is when a high-to-low transition on the SDA line occurs while SCL is high. The following byte is the address byte that consists of the 7-bit slave address followed by an $\mathrm{R} / \overline{\mathrm{W}}$ bit (this bit determines whether data is read from or written to the slave device).

The slave whose address corresponds to the transmitted address responds by pulling the SDA line low during the ninth clock pulse (this is termed the acknowledge bit). At this stage, all other devices on the bus remain idle while the selected device waits for data to be written to or read from its serial register. If the $\mathrm{R} / \overline{\mathrm{W}}$ bit is high, the master reads from the slave device. However, if the $\mathrm{R} / \overline{\mathrm{W}}$ bit is low, the master writes to the slave device.
2. Data is transmitted over the serial bus in sequences of nine clock pulses (eight data bits followed by an acknowledge bit). The transitions on the SDA line must occur during the low period of SCL and remain stable during the high period of SCL.
3. When all data bits have been read or written, a stop condition is established by the master. A stop condition is defined as a low-to-high transition on the SDA line while

SCL is high. In write mode, the master pulls the SDA line high during the $10^{\text {th }}$ clock pulse to establish a stop condition. In read mode, the master issues a no acknowledge for the ninth clock pulse (that is, the SDA line remains high). The master then brings the SDA line low before the $10^{\text {th }}$ clock pulse and then high during the $10^{\text {th }}$ clock pulse to establish a stop condition.
In the case of the AD5301/AD5311/AD5321, a write operation contains two bytes whereas a read operation may contain one or two bytes. See Figure 29 to Figure 34 for a graphical explanation of the serial interface.

A repeated write function gives the user flexibility to update the DAC output a number of times after addressing the part only once. During the write cycle, each multiple of two data bytes updates the DAC output. For example, after the DAC acknowledges its address byte, and receives two data bytes; the DAC output updates after the two data bytes, if another two data bytes are written to the DAC while it is still the addressed slave device. These data bytes also cause an output update. A repeat read of the DAC is also allowed.

## INPUT SHIFT REGISTER

The input shift register is 16 bits wide. Figure 26, Figure 27, and Figure 28 illustrate the contents of the input shift register for each part. Data is loaded into the device as a 16 -bit word under the control of a serial clock input, SCL. The timing diagram for this operation is shown in Figure 2. The 16-bit word consists of four control bits followed by $8 / 10 / 12$ bits of data, depending on the device type. MSB (Bit 15) is loaded first. The first two bits are don't cares. The next two are control bits that control the mode of operation of the device (normal mode or any one of three power-down modes). See the Power-Down Modes section for a complete description. The remaining bits are left justified DAC data bits, starting with the MSB and ending with the LSB.

## AD5301/AD5311/AD5321

## WRITE OPERATION

When writing to the AD5301/AD5311/AD5321 DACs, the user must begin with an address byte, after which the DAC acknowledges that it is prepared to receive data by pulling

SDA low. This address byte is followed by the 16 -bit word in the form of two control bytes. The write operations for the three DACs are shown in Figure 29 to Figure 31.

Figure 29. AD5301 Write Sequence

Figure 30. AD5311 Write Sequence

Figure 31. AD5321 Write Sequence

## AD5301/AD5311/AD5321

## READ OPERATION

When reading data back from the AD5301/AD5311/AD5321 DACs, the user must begin with an address byte after which the DAC acknowledges that it is prepared to transmit data by pulling SDA low. There are two different read operations. In the case of the AD5301, the readback is a single byte that consists of
the eight data bits in the DAC register. However, in the case of the AD5311 and AD5321, the readback consists of two bytes that contain both the data and the power-down mode bits. The read operations for the three DACs are shown in Figure 32 to Figure 34.

Figure 32. AD5301 Readback Sequence

Figure 33. AD5311 Readback Sequence

Figure 34. AD5321 Readback Sequence

## AD5301/AD5311/AD5321

## POWER-DOWN MODES

The AD5301/AD5311/AD5321 have very low power consumption, dissipating typically 0.36 mW with a 3 V supply and 0.75 mW with a 5 V supply. Power consumption can be further reduced when the DAC is not in use by putting it into one of three power-down modes, which are selected by Bit 13 and Bit 12 (PD1 and PD0) of the control word. Table 6 shows how the state of the bits corresponds to the mode of operation of the DAC.

Table 6. PD1 and PD0 Operating Modes

| PD1 | PD0 | Operating Mode |
| :--- | :--- | :--- |
| 0 | 0 | Normal operation |
| 0 | 1 | Power-down (1 k $\Omega$ load to GND) |
| 1 | 0 | Power-down (100 k $\Omega$ load to GND) |
| 1 | 1 | Power-down (three-state output) |

The software power-down modes programmed by PD1 and PD0 may be overridden by the $\overline{\mathrm{PD}}$ pin on the 8-lead version. Taking this pin low puts the DAC into three-state power-down mode. If $\overline{\mathrm{PD}}$ is not used, tie it high.

When both bits are set to 0 , the DAC works normally with its normal power consumption of $150 \mu \mathrm{~A}$ at 5 V , while for the three power-down modes, the supply current falls to 200 nA at 5 V ( 50 nA at 3 V ). Not only does the supply current drop, but the
output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the part is known while the part is in power-down mode and provides a defined input condition for whatever is connected to the output of the DAC amplifier. There are three different options. The output is connected internally to GND through a $1 \mathrm{k} \Omega$ resistor, a $100 \mathrm{k} \Omega$ resistor, or it is left three-stated. Resistor tolerance $= \pm 20 \%$. The output stage is illustrated in Figure 35.

Figure 35. Output Stage During Power-Down
The bias generator, the output amplifier, the resistor string, and all other associated linear circuitry are shut down when the power-down mode is activated. However, the contents of the DAC register are unchanged when in power-down. The time to exit power-down is typically $2.5 \mu \mathrm{~s}$ for $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$ and $6 \mu \mathrm{~s}$ when $V_{D D}=3 \mathrm{~V}$ (see Figure 21).

## AD5301/AD5311/AD5321

## APPLICATIONS NOTES

## USING REF19x AS A POWER SUPPLY

Because the supply current required by the AD5301/AD5311/ AD5321 is extremely low, the user has an alternative option to employ a REF195 voltage reference (for 5 V) or a REF193 voltage reference (for 3 V ) to supply the required voltage to the part (see Figure 36).

Figure 36. REF195 as Power Supply to AD5301/AD5311/AD5321
This is especially useful if the power supply is quite noisy or if the system supply voltages are at some value other than 5 V or 3 V (for example, 15 V). The REF193/REF195 output a steady supply voltage for the AD5301/AD5311/AD5321. If the low dropout REF195 is used, it needs to supply a current of $150 \mu \mathrm{~A}$ to the AD5301/AD5311/AD5321. This is with no load on the output of the DAC. When the DAC output is loaded, the REF195 also needs to supply the current to the load.

The total current required (with a $2 \mathrm{k} \Omega$ load on the DAC output and full scale loaded to the DAC) is

$$
150 \mu \mathrm{~A}+(5 \mathrm{~V} / 2 \mathrm{k} \Omega)=2.65 \mathrm{~mA}
$$

The load regulation of the REF195 is typically $2 \mathrm{ppm} / \mathrm{mA}$, which results in an error of $5.3 \mathrm{ppm}(26.5 \mu \mathrm{~V})$ for the 2.65 mA current drawn from it. This corresponds to a 0.00136 LSB error.

## BIPOLAR OPERATION USING THE AD5301/ AD5311/AD5321

The AD5301/AD5311/AD5321 has been designed for singlesupply operation, but a bipolar output range is also possible using the circuit in Figure 37. The circuit below gives an output voltage range of $\pm 5 \mathrm{~V}$. Rail-to-rail operation at the amplifier output is achievable using an AD820 or an OP295 as the output amplifier.

Figure 37. Bipolar Operation with the AD5301/AD5311/AD5321
The output voltage for any input code can be calculated as

$$
\left.V_{\text {OUT }}=\left[\left(V_{D D} \times\left(D / 2^{N}\right) \times R 1+R 2\right) / R 1\right)-V_{D D} \times(R 2 / R 1)\right]
$$

where:
$D$ is the decimal equivalent of the code loaded to the DAC. $N$ is the DAC resolution.

With $V_{D D}=5 \mathrm{~V}, \mathrm{R} 1=R 2=10 \mathrm{k} \Omega$,
$V_{\text {OUT }}=\left(10 \times D / 2^{N}\right)-5 \mathrm{~V}$

## MULTIPLE DEVICES ON ONE BUS

Figure 38 shows four AD5301 devices on the same serial bus. Each has a different slave address since the state of their A0 and A1 pins is different. This allows each DAC to be written to or read from independently. The master device output bus line drivers are open-drain, pull-downs in a fully $\mathrm{I}^{2} \mathrm{C}$-compatible interface.

## CMOS DRIVEN SCL AND SDA LINES

For single or multisupply systems where the minimum SCL swing requirements allow it, a CMOS SCL driver may be used, and the SCL pull-up resistor can be removed, making the SCL bus line fully CMOS compatible. This reduces power consumption in both the SCL driver and receiver devices. The SDA line remains open-drain, $\mathrm{I}^{2} \mathrm{C}$ compatible.

Further changes, in the SDA line driver, may be made to make the system more CMOS compatible and save more power. As the SDA line is bidirectional, it cannot be made fully CMOS compatible. A switched pull-up resistor can be combined with a CMOS device with an open-circuit (three-state) input such that the CMOS SDA driver is enabled during write cycles and $\mathrm{I}^{2} \mathrm{C}$ mode is enabled during shared cycles, that is, readback, acknowledge bit cycles, start conditions, and stop conditions.

## AD5301/AD5311/AD5321

## POWER SUPPLY DECOUPLING

In any circuit where accuracy is important, careful consideration of the power supply and ground return layout helps to ensure the rated performance. The AD5301/AD5311/AD5321 should be decoupled to GND with $10 \mu \mathrm{~F}$ in parallel with a $0.1 \mu \mathrm{~F}$ capacitor, located as close to the package as possible. The $10 \mu \mathrm{~F}$ capacitor should be the tantalum bead type, while
a ceramic $0.1 \mu \mathrm{~F}$ capacitor provides a sufficient low impedance path to ground at high frequencies. The power supply lines of the AD5301/AD5311/AD5321 should use as large a trace as possible to provide low impedance paths. A ground line routed between the SDA and SCL lines helps reduce crosstalk between them. This is not required on a multilayer board as there is a ground plane layer, but separating the lines helps.

## NOTES

## Стандарт Злектрон Связь

Мы молодая и активно развивающаяся компания в области поставок электронных компонентов. Мы поставляем электронные компоненты отечественного и импортного производства напрямую от производителей и с крупнейших складов мира.

Благодаря сотрудничеству с мировыми поставщиками мы осуществляем комплексные и плановые поставки широчайшего спектра электронных компонентов.

Собственная эффективная логистика и склад в обеспечивает надежную поставку продукции в точно указанные сроки по всей России.

Мы осуществляем техническую поддержку нашим клиентам и предпродажную проверку качества продукции. На все поставляемые продукты мы предоставляем гарантию.

Осуществляем поставки продукции под контролем ВП МО РФ на предприятия военно-промышленного комплекса России, а также работаем в рамках 275 ФЗ с открытием отдельных счетов в уполномоченном банке. Система менеджмента качества компании соответствует требованиям ГОСТ ISO 9001.

Минимальные сроки поставки, гибкие цены, неограниченный ассортимент и индивидуальный подход к клиентам являются основой для выстраивания долгосрочного и эффективного сотрудничества с предприятиями радиоэлектронной промышленности, предприятиями ВПК и научноисследовательскими институтами России.

С нами вы становитесь еще успешнее!
