

1/5-Inch 2 Mp CMOS Digital Image Sensor

MT9D015 Datasheet, Rev. M

For the latest datasheet, please visit www.onsemi.com

Features

- Superior low light performance
- High sensitivity
- Low dark current
- Simple two-wire serial interface
- Auto black level calibration
- Programmable controls: gain, frame size/rate, exposure, left–right and top–bottom image reversal, window size and panning
- Data interface: CCP2 compliant sub-low-voltage differential signaling (sub-LVDS) or single lane serial mobile industry processor interface (MIPI)
- SMIA 1.0 compatible; MIPI 1.0 compliant
- On-chip phase-locked loop (PLL) oscillator
- Bayer-pattern down-size scaler
- Integrated lens shading correction
- Internal power switch for ultra-low standby current consumption
- 30 fps at full resolution
- 2D defect pixel correction
- 2624-bit one-time programmable memory (OTPM) for storing module information and lens shading correction.

General Description

The ON Semiconductor MT9D015 is a 1/5-inch UXGA-format CMOS active-pixel digital image sensor with a pixel array of 1600H x 1200V (1608H x 1208V including border pixels). It incorporates sophisticated on-chip camera functions such as windowing, mirroring, column and subsampling modes. It is programmable through a simple two-wire serial interface and has very low power consumption.

Applications

- Cellular phones
- Digital still cameras
- PC cameras
- PDAs

General Description

The MT9D015 digital image sensor features ON Semiconductor's breakthrough low noise CMOS imaging technology that achieves near-CCD image quality (based on signal-to-noise ratio and low-light sensitivity) while maintaining the inherent size, cost, and integration advantages of CMOS.

When operated in its default mode, the sensor generates a UXGA image at 21 frames per second (fps) when ext_clk_freq_mhz = 16 MHz. An on-chip analog-to-digital converter (ADC) generates a 10-bit value for each pixel.

Functional Overview

The MT9D015 is a progressive-scan sensor that generates a stream of pixel data at a constant frame rate. It uses an on-chip, phase-locked loop (PLL) to generate all internal clocks from a single master input clock running between 6 and 27 MHz. The maximum pixel rate is 64 Mp/s, corresponding to a video timing pixel clock rate of 91.4 MHz. A block diagram of the sensor is shown in Figure 1.

Figure 1: Block Diagram

The core of the sensor is a 2Mp active-pixel array. The timing and control circuitry sequences through the rows of the array, resetting and then reading each row in turn. In the time interval between resetting a row and reading that row, the pixels in the row integrate incident light. The exposure is controlled by varying the time interval between reset and readout. Once a row has been read, the data from the columns is sequenced through an analog signal chain (providing offset correction and gain), and then through an ADC. The output from the ADC is a 10-bit value for each pixel in the array. The ADC output passes through a digital processing signal chain (which provides further data corrections and applies digital gain).

The pixel array contains optically active and light-shielded (dark) pixels. The dark pixels are used to provide data for on-chip offset-correction algorithms (black level control).

The sensor contains a set of control and status registers that can be used to control many aspects of the sensor behavior including the frame size, exposure, and gain setting. These registers can be accessed through a two-wire serial interface.

The output from the sensor is a Bayer pattern; alternate rows are a sequence of either green and red pixels or blue and green pixels. The offset and gain stages of the analog signal chain provide per-color control of the pixel data.

The control registers, timing and control, and digital processing functions shown in Figure 1 on page 6 are partitioned into three logical parts:

- A sensor core that provides array control and data path corrections.
- A digital shading correction block to compensate for color/brightness shading introduced by the lens or CRA curve mismatch.
- Functionality to support the SMIA standard. This includes a horizontal and vertical image scaler, a limiter, a data compressor, an output FIFO, and a serializer.

The output FIFO prevents data bursts by keeping the data rate continuous.

Pixel Array

The sensor core uses a Bayer color pattern, as shown in Figure 2. The even-numbered rows contain green and red pixels; odd-numbered rows contain blue and green pixels. Even-numbered columns contain green and blue pixels; odd-numbered columns contain red and green pixels.

Figure 2: Pixel Color Pattern Detail (Top Right Corner)

Operating Modes

The MT9D015 can operate in either serial CCP2 or serial MIPI mode (preconfigured at the factory). In both cases, the sensor has a SMIA-compatible register interface while the I^2C device address is compliant with SMIA or MIPI requirements as appropriate. The reset level on the TEST pin must be tied in a way that is compatible with the configured serial interface of the sensor, for instance TEST = 0 for CCP2 and TEST = 1 for MIPI.

Typical configurations are shown in Figure 3 and Figure 4 on page 9. These operating modes are described in "Control of the Signal Interface" on page 32.

For low-noise operation, the MT9D015 requires separate power supplies for analog and digital. Incoming digital and analog ground conductors can be tied together next to the die. Both power supply rails should be decoupled from ground using capacitors as close as possible to the die. The use of inductance filters is not recommended on the power supplies or output signals.

Figure 3: Typical Configuration (Connection) – Serial Output Mode

Notes: 1. All power supplies must be adequately decoupled.

- 2. A resistor value of $1.5k\Omega$ is recommended, but it may be greater for slower two-wire speed.
- 3. TEST must be tied to GND for SMIA configuration.
- 4. Also referred to as RESET BAR.
- 5. The GPI pins can be statically pulled HIGH or LOW and used as module IDs. All GPI pins must be driven to avoid leakage current.
- 6. ON Semiconductor recommends that 0.1μF and 1μF decoupling capacitors for each power supply are mounted as close as possible to the pad. Actual values and results may vary depending on layout and design considerations.

- 7. VPP, which can be used during the module manufacturing process, is not shown in Figure 3. This pad is left unconnected during normal operation.
- 8. ATEST1 and ATEST2 must be floating.

Figure 4: Typical Configuration (Connection) – MIPI Mode

Notes: 1. All power supplies must be adequately decoupled.

- 2. A resistor value of $1.5k\Omega$ is recommended, but it may be greater for slower two-wire speed.
- 3. TEST must be tied to VDD for MIPI configuration.
- 4. Also referred to as RESET BAR.
- 5. The GPI pins can be statically pulled HIGH or LOW and used as module IDs. All GPI pins must be driven to avoid leakage current.
- 6. ON Semiconductor recommends that 0.1µF and 1µF decoupling capacitors for each power supply are mounted as close as possible to the pad. Actual values and results may vary depending on layout and design considerations.
- 7. VPP, which can be used during the module manufacturing process, is not shown in Figure 3. This pad is left unconnected during normal operation.
- 8. ATEST1 and ATEST2 must be floating.

Signal Descriptions

Table 3 provides signal descriptions for MT9D015 die. For pad location and aperture information, refer to the MT9D015 die data sheet.

Table 3:Signal Descriptions

UN

| Pad Name | Pad Type | Description |
|--------------------------|----------|---|
| EXTCLK | Input | Master clock input. PLL input clock. 6–27 MHz. |
| RESET_BAR (XSHUTDOWN) | Input | Asynchronous active LOW reset. When asserted, data output stops and all internal registers are restored to their factory default settings. |
| Sclk | Input | Serial clock for access to control and status registers. |
| GPI[3:0] | Input | General purpose inputs. After reset, these pads are powered up (enabled—see R0x301A) by default; these pads must be bonded to a HIGH or LOW state. Failure to bond as required will result in excessive power consumption. |
| TEST | Input | Enable manufacturing test modes. Connect to DGND for normal operation of the CCP2-configured sensor, or connect to VDD power for the MIPI configured sensor. |
| Sdata | I/O | Serial data for reads from and writes to control and status registers. |
| DATA_P | Output | Differential CCP2/MIPI (sub-LVDS) serial data (positive). |
| DATA_N | Output | Differential CCP2/MIPI (sub-LVDS) serial data (negative). |
| CLK_P | Output | Differential CCP2/MIPI (sub-LVDS) serial clock/strobe (positive). |
| CLK_N | Output | Differential CCP2/MIPI (sub-LVDS) serial clock/strobe (negative). |
| VAA | Supply | Analog power supply. |
| VDD_PLL | Supply | PLL power supply. |
| VAA_PIX | Supply | Analog power supply. |
| Agnd | Supply | Analog ground. |
| Vdd | Supply | Digital power supply. |
| Dgnd | Supply | Digital ground. |
| VPP | Supply | OTPM programming power supply |

Two-Wire Serial Register Interface

ON

| | The two-wire serial interface bus enables read/write access to control and status regis- ters within the sensor. This interface is designed to be compatible with the SMIA 1.0 Part 2: CCP2 Specification camera control interface (CCI), which uses the electrical charac- teristics and transfer protocols of the I ² C specification. |
|-------------------------|---|
| | The protocols described in the I ² C specification allow the slave device to drive SCLK LOW; the sensor uses SCLK as an input only and therefore never drives it LOW. |
| Protocol | |
| | Data transfers on the two-wire serial interface bus are performed by a sequence of low-level protocol elements: 1. a (repeated) start condition 2. a slave address/data direction byte 3. an (a no) acknowledge bit 4. a message byte 5. a stop condition |
| | The bus is idle when both SCLK and SDATA are HIGH. Control of the bus is initiated with a start condition, and the bus is released with a stop condition. Only the master can generate the start and stop conditions. |
| Start Condition | |
| | A start condition is defined as a HIGH-to-LOW transition on SDATA while SCLK is HIGH. At the end of a transfer, the master can generate a start condition without previously generating a stop condition; this is known as a "repeated start" or "restart" condition. |
| Slave Address/Data Dire | ction Byte |
| | Bits [7:1] of this byte represent the device slave address and bit [0] indicates the data transfer direction. A "0" in bit [0] indicates a write, and a "1" indicates a read. The default slave addresses used by the MT9D015 for the MIPI configured sensor are 0x6C (write address) and 0x6D (read address) in accordance with the MIPI specification. But for the CCP2 configured sensor, the default slave addresses used are 0x20 (write address) and 0x21 (read address) in accordance with the SMIA specification. |
| Acknowledge Bit | |
| | Each 8-bit data transfer is followed by an acknowledge bit or a no-acknowledge bit in the SCLK clock period following the data transfer. The transmitter (which is the master when writing, or the slave when reading) releases SDATA. The receiver indicates an acknowledge bit by driving SDATA LOW. As for data transfers, SDATA can change when SCLK is LOW and must be stable while SCLK is HIGH. |
| No-Acknowledge Bit | |
| | The no-acknowledge bit is generated when the receiver does not drive SDATA LOW during the SCLK clock period following a data transfer. A no-acknowledge bit is used to terminate a read sequence. |
| Message Byte | |
| | Message bytes are used for sending register addresses and register write data to the slave device and for retrieving register read data. The protocol used is outside the scope of the SMIA CCI. |

| Stop Condition | |
|------------------|---|
| | A stop condition is defined as a LOW-to-HIGH transition on SDATA while SCLK is HIGH. |
| Data Transfer | |
| | Data is transferred serially, 8 bits at a time, with the MSB transmitted first. Each byte of data is followed by an acknowledge bit or a no-acknowledge bit. This data transfer mechanism is used for the slave address/data direction byte and for message bytes. |
| | One data bit is transferred during each SCLK clock period. SDATA can change when SCLK is LOW and must be stable while SCLK is HIGH. |
| Typical Sequence | |
| | A typical READ or WRITE sequence begins by the master generating a start condition on the bus. After the start condition, the master sends the 8-bit slave address/data direction byte. The last bit indicates whether the request is for a READ or a WRITE, where a "0" indicates a WRITE and a "1" indicates a READ. If the address matches the address of the slave device, the slave device acknowledges receipt of the address by generating an acknowledge bit on the bus. |
| | If the request was a READ, the master sends the 8-bit write slave address/data direction byte and 16-bit register address, just as in the write request. The master then generates a (re)start condition and the 8-bit READ slave address/data direction byte, and clocks out the register data, 8 bits at a time. The master generates an acknowledge bit after each 8-bit transfer. The slave's internal register address is automatically incremented after every 8 bits are transferred. The data transfer is stopped when the master sends a no-acknowledge bit. |

Single READ from Random Location

This sequence (Figure 5) starts with a dummy WRITE to the 16-bit address that is to be used for the READ. The master terminates the WRITE by generating a restart condition. The master then sends the 8-bit READ slave address/data direction byte and clocks out 1 byte of register data. The master terminates the READ by generating a no-acknowledge bit followed by a stop condition. Figure 5 shows how the internal register address maintained by the MT9D015 is loaded and incremented as the sequence proceeds.

Figure 5: Single READ from Random Location

| _ | | | Previous Reg Addre | ss, | N | X | Reg A | ddress, I | N | M+1 |
|--------------|---|-----|------------------------------------|-----|------------------|------|---------------|-----------|-----------|-----|

| P Si A | start condition stop condition restart condition acknowledge no-acknowledge | [| slave to master master to slave | | | | | | | |

Single READ from Current Location

This sequence (Figure 6) performs a read using the current value of the MT9D015 internal register address. The master terminates the READ by generating a no-acknowl-edge bit followed by a stop condition. The figure shows two independent read sequences.

Figure 6: Single READ from Current Location

Sequential READ, Start from Random Location

This sequence (Figure 7) starts in the same way as the single READ from random location (Figure 5). Instead of generating a no-acknowledge bit after the first byte of data has been transferred, the master generates an acknowledge bit and continues to perform byte reads until L bytes have been read.

Figure 7: Sequential READ, Start from Random Location

Sequential READ, Start from Current Location

This sequence (Figure 8) starts in the same way as the single READ from current location (Figure 6 on page 13). Instead of generating a no-acknowledge bit after the first byte of data has been transferred, the master generates an acknowledge bit and continues to perform byte reads until L bytes have been read.

Figure 8: Sequential READ, Start from Current Location

Single WRITE to Random Location

This sequence (Figure 9) begins with the master generating a start condition. The slave address/data direction byte signals a WRITE and is followed by the HIGH then LOW bytes of the register address that is to be written. The master follows this with the byte of write data. The WRITE is terminated by the master generating a stop condition.

Figure 9: Single WRITE to Random Location

Sequential WRITE, Start at Random Location

This sequence (Figure 10) starts in the same way as the single WRITE to random location (Figure 9). Instead of generating a stop condition after the first byte of data has been transferred, the master continues to perform byte writes until *L* bytes have been written. The WRITE is terminated by the master generating a stop condition.

Figure 10: Sequential Write, Start at Random Location

Registers

Note: The detailed register lists and descriptions are in a separate document, the MT9D015 Register Reference.

The MT9D015 provides a 32-bit register address space accessed through a serial interface ("Single READ from Random Location" on page 13). Each register location is 8 or 16 bits in size.

The address space is divided into the five major regions shown in Table 4.

Table 4:Address Space Regions

| Address Range | Description |
|---------------|--|
| 0x0000-0x0FFF | Configuration registers |
| | (read-only and read-write dynamic registers) |
| 0x1000-0x1FFF | Parameter limit registers |
| | (read-only static registers) |
| 0x2000–0x2FFF | Image statistics registers |
| | (none currently defined) |
| 0x3000–0x3FFF | Manufacturer-specific registers |
| | (read-only and read-write dynamic registers) |
| 0x4000–0xFFFF | Reserved (undefined) |

Register Notation

| | The underlying mechanism for reading and writing registers provides byte write capa- bility. However, it is convenient to consider some registers as multiple adjacent bytes. The MT9D015 uses 8-bit, 16-bit, and 32-bit registers, all implemented as 1 or more bytes at naturally aligned, contiguous locations in the address space. |
|------------------|---|
| | In this document, registers are described either by address or by name. When registers are described by address, the size of the registers is explicit. For example, R0x3024 is an 8-bit register at address 0x3024, and R0x3000–1 is a 16-bit register at address 0x3000–0x3001. When registers are described by name, refer to the register table to determine their size. |
| Register Aliases | |
| | A consequence of the internal architecture of the MT9D015 is that some registers are decoded at multiple addresses. Some registers in "configuration space" are also decoded in "manufacturer-specific space." To provide unique names for all registers, the name of the register within manufacturer-specific register space has a trailing underscore. For example, R0x0000–1 is model_id, and R0x3000–1 is model_id_ (see the register table for more examples). The effect of reading or writing a register through any of its aliases is identical. |
| Bit Fields | |
| | Some registers provide control of several different pieces of related functionality, making it necessary to refer to bit fields within registers. As an example of the notation used for this, the least significant 4 bits of the model_id register are referred to as model_id[3:0] or R0x0000–1[3:0]. |

| Bit Field Aliases | | |
|--------------------|---|--|
| | register fields a only one opera | the register aliases described in "Register Aliases" on page 15, some are aliased in multiple places. For example, R0x0100 (mode_select) has ational bit, R0x0100[0]. This bit is aliased to R0x301A–B[2]. The effect of ing a bit field through any of its aliases is identical. |
| Byte Ordering | | |
| | address in the l example, the m shown as 0x150 READ from add | beccupy more than 1 byte of address space are shown with the lowest highest-order byte lane to match the byte-ordering on the SMIA bus. For nodel_id register is R0x0000–1. In the register table the default value is 01. This means that a READ from address 0x0000 would return 0x15, and a dress 0x0001 would return 0x01. When reading this register as two 8-bit e serial interface, the 0x15 will appear on the serial interface first, followed |
| Address Alignment | | |
| | are aligned to e | resses are aligned naturally. Registers that occupy 2 bytes of address space even 16-bit addresses, and registers that occupy 4 bytes of address space 16-bit addresses that are an integer multiple of 4. |
| Bit Representation | | |

Register Behavior

Registers vary from "read-only," "read/write," and "read, write-1-to-clear."

Double-Buffered Registers

Some sensor settings cannot be changed during frame readout. For example, changing R0x0344–5 (x_addr_start) partway through frame readout would result in inconsistent row lengths within a frame. To avoid this, the MT9D015 double-buffers many registers by implementing a "pending" and a "live" version. READs and WRITEs access the pending register. The live register controls the sensor operation.

The value in the pending register is transferred to a live register at a fixed point in the frame timing, called frame start. Frame start is defined as the point at which the first dark row is read out internally to the sensor. In the register tables the "Sync'd" column shows which registers or register fields are double-buffered in this way.

Using grouped_parameter_hold

Register grouped_parameter_hold (R0x0104) can be used to inhibit transfers from the pending to the live registers. When the MT9D015 is in streaming mode, write "1" to this register before making changes to any group of registers where a set of changes is required to take effect simultaneously. When this register is set to "0," all transfers from pending to live registers take place on the next frame start.

An example of the consequences of failing to set this bit follows:

An external auto exposure algorithm might want to change both gain and integration time between two frames. If the next frame starts between these operations, it will have the new gain, but not the new integration time, which would return a frame with the wrong brightness that might lead to a feedback loop with the AE algorithm resulting in flickering.

Bad Frames

A bad frame is a frame where all rows do not have the same integration time or where offsets to the pixel values have changed during the frame.

Many changes to the sensor register settings can cause a bad frame. For example, when line_length_pck (R0x0342–3) is changed, the new register value does not affect sensor behavior until the next frame start. However, the frame that would be read out at that frame start will have been integrated using the old row width, so reading it out using the new row width would result in a frame with an incorrect integration time.

In the register tables, the "Bad Frame" column shows where changing a register or register field will cause a bad frame. The following notation is used:

N—No. Changing the register value will not produce a bad frame.

Y—Yes. Changing the register value might produce a bad frame.

YM—Yes; but the bad frame will be masked out when mask_corrupted_frames (R0x0105) is set to "1."

Changes to Integration Time

If the integration time is changed while FRAME_VALID (FV) is asserted for frame n, the first frame output using the new integration time is frame (n + 2). The sequence is as follows:

- 1. During frame *n*, the new integration time is held in the pending register.
- 2. At the start of frame (n + 1), the new integration time is transferred to the live register. Integration for each row of frame (n + 1) has been completed using the old integration time.
- 3. The earliest time that a row can start integrating using the new integration time is immediately after that row has been read for frame (n + 1). The actual time that rows start integrating using the new integration time is dependent upon the new value of the integration time.
- 4. When frame (n + 2) is read out, it will have been integrated using the new integration time.

If the integration time is changed on successive frames, each value written will be applied for a single frame; the latency between writing a value and it affecting the frame readout remains at two frames.

Changes to Gain Settings

Usually, when the gain settings are changed, the gain is updated on the next frame start. When the integration time and the gain are changed at the same time, the gain update is held off by one frame so that the first frame output with the new integration time also has the new gain applied. In this case, a new gain should not be set during the extra frame delay. There is an option to turn off the extra frame delay by setting reset_reg-ister[14] bit.

Embedded Data

The current values of implemented registers in the address range 0x0000–0x0FFF can be generated as part of the pixel data. This embedded data is enabled by default when the serial pixel data interface is enabled.

The current value of a register is the value that was used for the image data in that frame. In general, this is the live value of the register. The exceptions are:

- The integration time is delayed by one further frame, so that the value corresponds to the integration time used for the image data in the frame. See "Changes to Integration Time" on page 18.
- The PLL timing registers are not double-buffered, because the result of changing them in streaming mode is undefined. Therefore, the pending and live values for these registers are equivalent.

Embedded Data Format and Control

When the serial pixel data path is selected, the first two rows of the output image contain register values that are appropriate for the image. In this mode, the first two lines and the last line of data are not equally spaced. The format of this data is shown in Table 6. In the table, 8-bit (RAW8) and 10-bit (RAW10) versions of the data are shown. The 10-bit format places the data byte in bits [9:2] and sets bits [1:0] to a constant value of 01. Register values that are shown as "??" are dynamic and may change from frame to frame.

When the parallel pixel data path is selected and R0x306E-F[2:0]= 2 (parallel pixel data output MUX selects FIFO data). The output image contains two rows of embedded data.

Programming Restrictions

The SMIA specification imposes a number of programming restrictions. An implementation naturally imposes additional restrictions. Table 7 shows a list of programming rules that must be adhered to for correct operation of the MT9D015. ON Semiconductor recommends that these rules are encoded into the device driver stack—either implicitly or explicitly.

Table 7:Definitions for Programming Rules

| Name | Definition |
|-------|---|
| xskip | <pre>xskip = 1 if x_odd_inc = 1; xskip = 2 if x_odd_inc = 3</pre> |
| yskip | <pre>yskip = 1 if y_odd_inc = 1; yskip = 2 if y_odd_inc = 3</pre> |

Table 8: Programming Rules

| Table 8: | Programming Rules (continued) |
|----------|-------------------------------|
|----------|-------------------------------|

| Parameter | Minimum Value | Maximum Value | Origin | |
|------------------|---|--------------------|---|--|
| x_odd_inc[0] | 1 | 1 | SMIA | |
| y_odd_inc | min_odd_inc | max_odd_inc | SMIA | |
| y_odd_inc[0] | 1 | 1 | SMIA | |
| scale_m | scaler_m_min | scaler_m_max | SMIA | |
| scale_n | scaler_n_min | scaler_n_max | SMIA | |
| x_output_size | 256 | 1608 | Minimum from SMIA FS Section 5.2.2.5. Maximum is a consequence of the output FIFO size on this implementation. | |
| x_output_size[0] | 0 (this is enforced in hardware: bit[0] is read-only) | 0 | SMIA FS Section 5.2.2.2. | |
| y_output_size | 2 | frame_length_lines | Minimum ensures 1 Bayer row-pair. Maximum avoids output frame being longer than pixel array frame. | |
| y_output_size[0] | 0 (this is enforced in hardware: bit[0] is read-only) | 0 | SMIA FS Section 5.2.2.2 | |

Notes: 1. With subsampling, start and end pixels must be addressed (impact on x/y start/end addresses, function of image orientation bits). SMIA FS Errata see "Subsampling" on page 44.

Output Size Restrictions

The SMIA CCP2 specification imposes the restriction that an output line shall be a multiple of 32 bits in length. This imposes an additional restriction on the legal values of x_output_size:

- When ccp_format[7:0] = 8 (RAW8 data), x_output_size must be a multiple of 4 (x_output_size[1:0] = 0).
- When ccp_format[7:0] = 10 (RAW10 data), x_output_size must be a multiple of 16 (x_output_size[3:0] = 0).

This restriction can be met by rounding up x_output_size to an appropriate multiple. Any extra pixels in the output image as a result of this rounding contain undefined pixel data but are guaranteed not to cause false synchronization on the CCP2 data stream.

There is an additional restriction that x_output_size must be small enough such that the output row time (set by x_output_size, the framing and CRC overhead of 12 bytes, the ccp_signalling_mode and the output clock rate) must be less than the row time of the video array (set by line_length_pck and the video timing clock rate).

Effect of Scaler on Legal Range of Output Sizes

When the scaler is enabled, it is necessary to adjust the values of x_output_size and y_output_size to match the image size generated by the scaler. The MT9D015 will not operate properly if the x_output_size and y_output_size are significantly larger than the output image. To understand the reason for this, consider the situation where the sensor is operating at full resolution and the scaler is enabled with a scaling factor of 32 (half the number of pixels in each direction). This situation is shown in Figure 11.

Figure 11: Effect of Limiter on the SMIA Data Path

 $\label{eq:limiter} Limiter \ output: \ scaled \ to \ half \ size, \ x_output_size = x_addr_end \ - \ x_addr_start \ + \ 1$

| LINE_VALID | |
|-------------|---|
| PIXEL_VALID | - |

In Figure 11, three different stages in the SMIA data path (see "Digital Data Path" on page 61) are shown. The first stage is the output of the sensor core. The core is running at full resolution and x_output_size is set to match the active array size. The LINE_VALID (LV) signal is asserted once per row and remains asserted for *N* pixel times. The PIXEL_VALID signal toggles with the same timing as LV, indicating that all pixels in the row are valid.

The second stage is the output of the scaler, when the scaler is set to reduce the image size by one-half in each dimension. The effect of the scaler is to combine groups of pixels. Therefore, the row time remains the same, but only half the pixels out of the scaler are valid. This is signalled by transitions in PIXEL_VALID. Overall, PIXEL_VALID is asserted for (N/2) pixel times per row.

The third stage is the output of the limiter when the x_output_size is still set to match the active array size. Because the scaler has reduced the amount of valid pixel data without reducing the row time, the limiter attempts to pad the row with (N/2) additional pixels. If this has the effect of extending LV across the whole of the horizontal blanking time, the MT9D015 will cease to generate output frames.

A correct configuration is shown in Figure 12 on page 30, in addition to showing the x_output_size reduced to match the output size of the scaler. In this configuration, the output of the limiter does not extend LV.

Figure 12 on page 30 also shows the effect of the output FIFO, which forms the final stage in the SMIA data path. The output FIFO merges the intermittent pixel data back into a contiguous stream. Although not shown in this example, the output FIFO is also capable of operating with an output clock that is at a different frequency from its input clock.

Figure 12: Timing of SMIA Data Path

Effect of CCP2 Class on Legal Range of Output Sizes/Frame Rate

The pixel array readout rate is set by *line_length_pck x frame_length_lines*. With the default register values, one frame time takes 2360 x 1283 = 3027880 pixel periods. This value includes vertical and horizontal blanking times so that the full-size image 1600 x 1202 (1200 lines of pixel data, 2 lines of embedded information) forms a subset of these pixels.

When the internal clock is running at 64 MHz, this frame time corresponds to *3027880/64e6* = *47.31* ms, giving rise to a frame rate of 21.14 fps.

Each pixel is 10 bits, by default. As a result, the serial data rate is required to transmit faster than the pixel rate. However, the SMIA CCP2 class 2 specifications has a maximum of 650 Mb/s, which cannot be exceeded.

The SMIA CCP2 specification shows that class 0 (data/clock) runs up to 208 Mb/s. Therefore, it is not possible to transmit full-resolution images at 15 fps using CCP2 class 0. Changing the ccp_data_format (to use 8 bits per pixel) reduces the bandwidth requirement, but is not enough to allow full-resolution operation.

The only way to get a full image out is to reduce the pixel clock rate until it is appropriate for the maximum CCP2 class 0 data rate. This requires the pixel rate to be reduced to 20.8 MHz. This has the side effect of reducing the frame rate. Repeating the calculation above, at 20.8 MHz internal clock, this corresponds to *3027880/20.8e6* = *14*5 ms, giving rise to a frame rate of 6.87 fps.

To use CCP2 class 0 with an internal clock of 64 MHz, it is necessary to reduce the amount of output data. This can be achieved by changing x_output_size, y_output_size so that less data comes out per frame. A change to the output size can be done in conjunction with windowing the image from the sensor (by adjusting x_addr_start, x_addr_end, y_addr_start, y_addr_end) or by enabling the scaler.

Output Data Timing

The output FIFO acts as a boundary between two clock domains. Data is written to the FIFO in the VT (video timing) clock domain. Data is read out of the FIFO in the OP (output) clock domain.

When the scaler is disabled, the data rate in the VT clock domain is constant and uniform during the active period of each pixel array row readout. When the scaler is enabled, the data rate in the VT clock domain becomes intermittent, corresponding to the data reduction performed by the scaler.

Maximum frame rate is achieved by setting the video timing clock (vt_clk_freq_mhz) to 91 MHz and using the FIFO to reduce horizontal blanking data rate to 640 Mb/s. At this setting, a maximum frame rate of 30 fps can be achieved.

A key constraint when configuring the clock for the output FIFO is that the frame rate out of the FIFO must exactly match the frame rate into the FIFO. When the scaler is disabled, this constraint can be met by imposing the rule that the row time on the CCP2 data stream must be greater than or equal to the row time at the pixel array. The row time on the CCP2 data stream is calculated from the x_output_size and the ccp_data_format (8 or 10 bits per pixel), and must include the time taken in the CCP2 data stream for start of frame/row, end of row/frame and checksum symbols.

Caution If this constraint is not met, the FIFO will either underrun or overrun. FIFO underrun or overrun is a fatal error condition that is signalled through the data path_status register (R0x306A).

Changing Registers while Streaming

The following registers should only be reprogrammed while the sensor is in software standby:

- ccp2_channel_identifier
- ccp2_signalling_mode
- ccp_data_format
- scale_m
- vt_pix_clk_div
- vt_sys_clk_div
- pre_pll_clk_div
- pll_multiplier
- op_pix_clk_div
- op_sys_clk_div

Control of the Signal Interface

This section describes the operation of the signal interface in all functional modes.

Serial Register Interface

The serial register interface uses the following signals:

- SCLK
- SDATA

SCLK is an input-only signal and must always be driven to a valid logic level for correct operation; if the driving device can place this signal in High-Z state, an external pull-up resistor should be connected on this signal.

SDATA is a bidirectional signal. An external pull-up resistor should be connected on this signal.

This interface is described in detail in "EXTCLK" on page 66.

Default Power-Up State

The MT9D015 provides interfaces for pixel data through the CCP2 high-speed serial interface described by the SMIA specification or the MIPI serial interface.

At power up and after a hard or soft reset, the reset state of the MT9D015 is to enable the SMIA CCP2 high speed serial interface for a CCP2-configured sensor, and CSI-2 high speed serial interface for a MIPI-configured sensor.

The CCP2 and MIPI serial interfaces share pins, and only one can be enabled at time. This is done at the factory.

Serial Pixel Data Interface

The serial pixel data interface uses the following output-only signal pairs:

- DATA_P
- DATA_N
- CLK_P
- CLK_N

The signal pairs are driven differentially using sub-LVDS switching levels. This interface conforms to the MIPI 1.0 CSI-2 and SMIA CCP2 requirements and supports both data/ clock signalling and data/strobe signalling.

The serial pixel data interface is enabled by default at power up and after reset. DATA_P and DATA_N are the data pair for the CCP2 or MIPI serial interface.

The DATA_P, DATA_N, CLK_P, and CLK_N pads are turned off if the SMIA serial disable bit is asserted (R0x301A–B[12] = 1) or when the sensor is in the soft standby state.

In data/clock mode, the clock remains HIGH when no data is being transmitted. In data/ strobe mode before frame start, clock is LOW and data is HIGH.

R0x0112-3 (ccp_data_format) The following data formats are supported:

• 0x0A0A – sensor supports RAW10 uncompressed data format.

• 0x0808 – sensor supports RAW8 uncompressed data format. A sensor with a 10-bit ADC can support this mode by discarding all but the upper 8 bits of a pixel value.

• 0x0A08 – sensor supports RAW8 data format in which an adaptive compression algorithm is used to perform 10-bit to 8-bit compression on the upper 10 bits of each pixel value.

Also, the ccp_serial_format register (R0x31AE) register controls which serial interface is in use when the serial interface is enabled (reset_register[12] = 0). The following serial formats supported:

- 0x0101 sensor supports single-lane CCP2 operation.
- 0x0201 sensor supports single-lane MIPI operation.

System States

The system states of the MT9D015 are represented as a state diagram in Figure 13 and described in subsequent sections. The effect of RESET_BAR on the system state and the configuration of the PLL in the different states are shown in Table 9 on page 35.

The sensor's operation is broken down into three separate states: hardware standby, soft standby, and streaming. The transition between these states might take a certain amount of clock cycles as outlined in Table 9.

Figure 13: MT9D015 System States

Table 9:PLL in System States

| State | EXTCLKs | PLL | |
|-------------------------|---------|--|--|
| Powered off | | | |
| Hardware standby | | | |
| POR active | | | |
| Internal initialization | 1200 | VCO powered down | |
| Software standby | | | |

Note: VCO = voltage-controlled oscillator.

Power-On Reset Sequence

When power is applied to the MT9D015, it enters a low-power hardware standby state. Exit from this state is controlled by the later of two events:

- 1. The negation of the RESET_BAR input.
- 2. A timeout of the internal power-on reset circuit.

It is possible to hold RESET_BAR permanently negated and rely upon the internal power-on reset circuit.

When RESET_BAR is asserted, it asynchronously resets the sensor, truncating any frame that is in progress.

When the sensor leaves the hardware standby state, it waits for power-on reset and performs an internal initialization sequence that takes 1200 EXTCLK cycles. After this time, it enters a low-power soft standby state. While the initialization sequence is in progress, the MT9D015 will not respond to READ transactions on its two-wire serial interface. Therefore, a method to determine when the initialization sequence has completed is to poll a sensor register; for example, R0x0000. While the initialization sequence is in progress, the sensor will not respond to its device address and READs from the sensor will result in a NACK on the two-wire serial interface bus. When the sequence has completed, READs will return the operational value for the register (0x1501 if R0x0000 is read).

When the sensor leaves soft standby mode and enables the VCO, an internal delay will keep the PLL disconnected for up to 16000 EXTCLKs so that the PLL can lock.

Soft Reset Sequence

The MT9D015 can be reset under software control by writing "1" to software_reset (R0x0103). A software reset asynchronously resets the sensor, truncating any frame that is in progress. The sensor starts the internal initialization sequence, while the PLL and analog blocks are turned off. At this point, the behavior is exactly the same as for the power-on reset sequence.

Signal State During Reset

Table 10 shows the state of the signal interface during hardware standby (RESET_BAR asserted) and the default state during soft standby (after exit from hardware standby and before any registers within the sensor have been changed from their default power-up values).

Table 10:Signal State During Reset

| Pad Name | Pad Type | Hardware Standby | Software Standby |
|--------------------------|----------|---|--|
| EXTCLK | Input | Self-biased. Can be left disconnected/floating. | |
| RESET_BAR (XSHUTDOWN) | Input | Enabled. Must be driven to a valid logic level. | |
| Sclk | Input | Enabled. Must be pulled up or driven to a valid logic level. | |
| Sdata | I/O | Enabled as an input. Must be pulled up or driven to a valid logic level. | |
| DATA_P | Output | | |
| DATA_N | Output | CCP2: High-Z MIPI: Ultra Low-Power State (ULPS), represented as an LP-00 state on the output (both wires at 0V) | |
| CLK_P | Output | | |
| CLK_N | Output | | |
| GPI[3:0] | Input | Powered up. Must be c | onnected to VDD or DGND. |
| TEST | Input | | ogic 0 for a serial CCP2-configured I MIPI-configured sensor. |

General Purpose Inputs

The MT9D015 provides four general purpose inputs. After reset, the input pads associated with these signals are powered on by default, requiring the pads to be tied to a defined logic level.

The general purpose inputs are disabled by setting reset_register[8] (R0x301A–B). Once disabled, the inputs can be left floating. The state of the general purpose inputs can be read through gpi_status[3:0] (R0x3026–7).

Streaming/Standby Control

The MT9D015 can be switched between its soft standby and streaming states under register control, as shown in Table 11. The state diagram for transitions between soft standby and streaming states is shown in Figure 13 on page 34.

Table 11: Streaming/STANDBY

| Streaming R0x301A–B[2] or R0x0100[0] | Description | |
|--------------------------------------|--------------|--|
| 0 | Soft standby | |
| 1 | Streaming | |

Clocking

The MT9D015 contains a PLL for timing generation and control. The PLL contains a prescaler to divide the input clock applied on EXTCLK, a VCO to multiply the prescaler output, and a set of dividers to generate the output clocks.

Profile 0 Behavior

i

ON Semiconductor SMIA sensors are profile 2 sensors and have separate video timing and output clock domains.

If the video timing and output clock domains are programmed with the same dividers, the part will operate in profile 0 mode as indicated by R0x306E–F[7]. For example, if Equation 1 is true, then the PLL will have profile 0 behavior:

$$Profile0_behavior = (vt_sys_clk_div == op_sys_clk_div)$$
(EQ 1)
& (vt_pix_clk_div == op_pix_clk_div)

When the PLL is programmed to be in profile 0 behavior then the output clock domain is connected internally to the video timing domain thus ensuring that the sensor behave as an profile 0 sensor with respect to the PLL.

In profile 0 mode the number of bits between one sync code and the subsequent one are guaranteed to be equal.

Note that legacy sensors used the profile bit in the datapath_select register R0x306E[7] to set this behavior. The new behavior of profile 0 mode is equivalent with the old one once it is set by the host system.

Figure 14: MT9D015 SMIA Profile 1/2 Clocking Structure

- Notes: 1. The combinations vt_sys_clk_div = 1 and vt_pix_clk_div = (4,5, 6,... 16) are also supported even though the capability register does not advertise this.
 - 2. The pll_multiplier only accepts even values when ccp2_class is set to data/clock signalling. Odd values will be rounded down to the first even number by setting LSB to "0."
 - 3. The default value for vt_sys_clk_div is outside the range of legal values defined by the capability registers. This results in correct behavior for the cases listed in Note 1. The default setting is selected to ensure profile 0 behavior as default with the highest possible frame rate.

The parameter limit register space contains registers that declare the minimum and maximum allowable values for:

- The frequency allowable on each clock
- The divisors that are used to control each clock

The following factors determine what are valid values, or combinations of valid values, for the divider/multiplier control registers:

- The minimum/maximum frequency limits for the associated clock must be met.
- The minimum/maximum value for the divider/multiplier must be met.
- The value of pll_multiplier should be a multiple of 2 for Data/Strobe signalling.
- The op_pix_clk must never run faster than the vt_pix_clk to ensure that the CCP2 output data stream is contiguous.
- Given the maximum programmed line length, the minimum blanking time, the maximum image width, the available PLL divisor/multiplier values, and the requirement that the output line time (including the necessary blanking) must be output in a time equal to or less than the time defined by line_length_pck, the valid combinations of the clock divisors.

PLL input clock frequency range, after the pre-PLL divider stage, is 2.0–24 MHz.

The usage of the output clocks is:

• vt_pix_clk is used by the sensor core to control the timing of the pixel array. The sensor core produces one 10-bit pixel each vt_pix_clk period. The line length

(line_length_pck) and fine integration time (fine_integration_time) are controlled in increments of the vt_pix_clk period.

- op_pix_clk is used to load parallel pixel data from the output FIFO (see Figure 26 on page 61) to the CCP2 serializer. The output FIFO generates one pixel each op_pix_clk period. The pixel is either 8-bit or 10-bit depending upon the output data format, controlled by R0x0112-3 (ccp_data_format).
- op_sys_clk is used to generate the serial data stream on the CCP2 output. The relationship between this clock frequency and the op_pix_clk frequency is dependent upon the output data format.

In profile 1/2, the output clock frequencies can be calculated as:

$$vt_pix_clk_freq_mhz = \frac{ext_clk_freq_mhz*pll_multiplier}{pre_pll_clk_div*vt_sys_clk_div*vt_pix_clk_div}$$
(EQ 2)

$$op_pix_clk_freq_mhz = \frac{ext_clk_freq_mhz*pll_multiplier}{pre_pll_clk_div*op_sys_clk_div*op_pix_clk_div}$$
(EQ 3)

$$op_sys_clk_freq_mhz = \frac{ext_clk_freq_mhz*pll_multiplier}{pre_pll_clk_div*op_sys_clk_div}$$
(EQ 4)

Figure 15: MT9D015 SMIA Profile 0 Clocking Structure

- Notes: 1. The legal range yielding profile 0 behavior is limited to the PLL values where the "vt domain" equals the "op domain". The vt_sys_clk_div values in the parentheses are therefore the legal values for both vt_sys_clk_div and op_sys_clk_div, and the vt_pix_clk_div values in the parentheses are legal values for both vt_pix_clk_div and op_pix_clk_div.
 - 2. The default value for vt_sys_clk_div is outside the range of legal values defined by the capability registers. This will result in correct behavior for the cases listed in Note 1. The default setting is selected to ensure profile 0 behavior as default with the highest possible frame rate.

When the video timing domain and the output timing domain have the same divider values, the PLL is equivalent to the SMIA profile 0 clocking structure. This is achieved by driving the op_sys_clk domain from the vt_sys_clk output and by driving the op_pix_clk domain from the vt_pix_clk output.

Programming the PLL Divisors

The PLL divisors should be programmed while the MT9D015 is in the soft standby state. After programming the divisors, it is necessary to wait for the VCO lock time before enabling the PLL. The PLL is enabled by entering the streaming state.

An external timer needs to delay the entering of streaming mode by 1ms so that the PLL can lock.

The effect of programming the PLL divisors while the MT9D015 is in the streaming state is undefined.

Influence of ccp_data_format

R0x0112-3 (ccp_data_format) controls whether the pixel data interface will generate 10 bits per pixel or 8 bits per pixel. The raw output of the sensor core is 10 bits per pixel; the two 8-bit modes represent a compressed data mode and a mode in which the two least significant bits of the 10-bit data are discarded.

When the pixel data interface is generating 8 bits per pixel, op_pix_clk_div must be programmed with the value 8. When the pixel data interface is generating 10 bits per-pixel, op_pix_clk_div must be programmed with the value 10.

Features

Lens Shading Correction (LC)

Lenses tend to produce images whose brightness is significantly attenuated near the edges. There are also other factors causing fixed pattern signal gradients in images captured by image sensors. The cumulative result of all these factors is known as image shading. The MT9D015 has an embedded shading correction module that can be programmed to counter the shading effects on each individual Red, GreenB, GreenR, and Blue color signal.

The Correction Function

Color-dependent solutions are calibrated using the sensor, lens system, and an image of an evenly illuminated, featureless grey calibration field. From the resulting image the color correction functions can be derived.

The correction functions can then be applied to each pixel value to equalize the response across the image as follows:

$$Pcorrected(row, col) = Psensor(row, col) * f(row, col)$$
 (EQ 5)

where P are the pixel values and f is the color-dependent correction function for each color channel.

Each function includes a set of color-dependent coefficients defined by registers R0x3600–3726. The function's origin is the center point of the function used in the calculation of the coefficients. Using an origin near the central point of symmetry of the sensor response provides the best results.

The correct sequence to write to the LC registers is as follows:

- 1. Set R0x3780 1 = 0x0000.
- 2. Load LC coefficients.
- 3. Set R0x3780 1 = 0x8000.

To read the LC coefficients, disable LC (set R0x3780-1 = 0x0000) before reading the register values.

One-Time Programmable Memory (OTPM)

The MT9D015 has 2624 bits of OTP memory that can be used during module manufacturing to store specific module information. This feature enables system integrators and module manufacturers to label and distinguish various module types based on lenses, IR-cut filters, or other properties. MT9D015 can support one set of LSC to save in OTPM. For OTPM programming details, please refer TN-09-248.

Figure 16: OTPM Block Diagram

Image Acquisition Modes

| | The MT9D015 supports ERS mode. When the MT9D015 is streaming, it generates frames at a fixed rate, and each frame is integrated (exposed) using the ERS. Timing and control logic within the sensor sequences through the rows of the array, resetting and then reading each row in turn. In the time interval between resetting a row and subsequently reading that row, the pixels in the row integrate incident light. The integration (exposure) time is controlled by varying the time between row reset and row readout. For each row in a frame, the time between row reset and row readout is fixed, leading to a uniform integration time across the frame. When the integration time is changed (by using the two-wire serial interface to change register settings), the timing and control logic controls the transition from old to new integration time in such a way that the stream of output frames from the MT9D015 switches cleanly from the old integration time to the new while only generating frames with uniform integration. |
|----------------|--|
| Window Control | |
| | The sequencing of the pixel array is controlled by the x_addr_start, y_addr_start, x_ad- dr_end, and y_addr_end registers. The output image size is controlled by the x_output size and y_output_size registers. |
| Pixel Border | |
| | The default settings of the sensor provide a 1600H x 1200V image. A border of up to 4 pixels on each edge can be enabled by reprogramming the x_addr_start, y_addr_start, x_addr_end, y_addr_end, and x_output_size and y_output_size registers accordingly. |

Full Resolution Frame Structure With Embedded Data

Figure 17 shows a full resolution frame structure example. The embedded data enable or disable is controlled by R0x3064[8], when set the bit to "1", two lines of embedded data will output on start of image frame.

Figure 17: Full Resolution Frame Structure Example

Readout Modes

Horizontal Mirror

When the horizontal_mirror bit is set in the image_orientation register, the order of pixel readout within a row is reversed, so that readout starts from x_addr_end and ends at x_addr_start. Figure 18 shows a sequence of 6 pixels being read out with horizon-tal_mirror = 0 and horizontal_mirror = 1. Changing horizontal_mirror causes the Bayer order of the output image to change; the new Bayer order is reflected in the value of the pixel_order register.

Figure 18: Effect of horizontal_mirror on Readout Order

Vertical Flip

When the vertical_flip bit is set in the image_orientation register, the order in which pixel rows are read out is reversed, so that row readout starts from y_addr_end and ends at y_addr_start. Figure 19 shows a sequence of 6 rows being read out with vertical_flip = 0 and vertical_flip = 1. Changing vertical_flip causes the Bayer order of the output image to change; the new Bayer order is reflected in the value of the pixel_order register.

Figure 19: Effect of vertical_flip on Readout Order

Subsampling

The MT9D015 supports subsampling. Subsampling reduces the amount of data processed by the analog signal chain in the MT9D015 thereby allowing the frame rate to be increased. Subsampling is enabled by setting x_odd_inc and/or y_odd_inc. Values of 1 and 3 can be supported. Setting both of these variables to 3 reduces the amount of row and column data processed. Figure 20 shows a sequence of 8 columns being read out with x_odd_inc = 3 and y_odd_inc = 1.

Figure 20: Effect of x_odd_inc = 3 on Readout Sequence

Figure 21: Pixel Readout (No Subsampling)

Figure 22: Pixel Readout (x_odd_inc = 3, y_odd_inc = 3)

Programming Restrictions when Subsampling

When subsampling is enabled as a viewfinder mode and the sensor is switched back and forth between full resolution and subsampling, ON Semiconductor recommends that line_length_pck be kept constant between the two modes. This allows the same integration times to be used in each mode.

When subsampling is enabled, it may be necessary to adjust the x_addr_end, x_addr_start and y_addr_end settings: the values for these registers are required to correspond with rows/columns that form part of the subsampling sequence. The adjustment should be made in accordance with the following rules:

• x_addr_start must be a multiple of 2 for example 0, 4, 6, 8, and x_addr_start = 2 is not supported

Example:

To achieve 1600 x 1200 full resolution without subsampling, the recommended register settings are:

[full resolution starting address with (4, 4)] //GROUPED_PARAMETER_HOLD REG=0x0104, 1 //X_ODD_INC REG=0x0382, 1 REG=0x0386, 1 //Y_ODD_INC //X_ADDR_START REG=0x0344, 4 REG=0x0346, 4 //Y_ADDR_START //X_ADDR_END REG=0x0348, 1603 REG=0x034A, 1203 //Y_ADDR_END //X_OUTPUT_SIZE REG=0x034C, 1600 //Y_OUTPUT_SIZE REG=0x034E, 1200 //GROUPED_PARAMETER_HOLD REG=0x0104, 0

To achieve a 800 x 600 resolution with 1/2 subsampling, the recommended register settings are:

|] |
|--------------------------|
| //GROUPED_PARAMETER_HOLD |
| //X_ODD_INC |
| //Y_ODD_INC |
| //X_ADDR_START |
| //Y_ADDR_START |
| //X_ADDR_END |
| //Y_ADDR_END |
| // X_OUTPUT_SIZE |
| //Y_OUTPUT_SIZE |
| //GROUPED_PARAMETER_HOLD |
| |

Table 12 shows the row address sequencing for normal and subsampled readout. The same sequencing applies to column addresses for subsampled readout. There are two possible subsampling sequences for the rows (because the subsampling sequence only read half of the rows) depending upon the alignment of the start address.

Table 12: Row Address Sequencing

| odd_inc = 1 | odd_inc = 3 | | |
|-------------|-------------|-----------|--|
| Normal | Normal | | |
| start = 0 | start = 0 | start = 2 | |
| 0 | 0 | | |
| 1 | 1 | | |

| 13 | 13 | | |
| 14 | | 14 | |
| 15 | | 15 | |

Frame Rate Control

The formula for calculating the frame rate of the MT9D015 are shown below:

$$line_length_pck = \left(\frac{x_addr_end - x_addr_start + x_odd_inc}{subsampling factor} + min_line_blanking_pck\right)$$
(EQ 6)

$$frame_length_lines = \left(\frac{y_addr_end - y_addr_start + y_odd_inc}{subsampling factor} + min_frame_blanking_lines\right) \quad (EQ 7)$$

$$frame \ rate \ [FPS] = \frac{(vt_pixel_clock_mhz * 1 \times 10^{6})}{(line_length_pck* frame_length_lines)}$$
(EQ 8)

Note: Subsampling factor = xskip or yskip xskip = 1 if x_odd_inc = 1; xskip = 2 if x_odd_inc = 3 yskip = 1 if y_odd_inc = 1; yskip = 2 if y_odd_inc = 3

Minimum Row Time

The minimum row time and blanking values with default register settings are shown in Table 13.

Table 13: Minimum Row Time and Blanking Numbers

| row_speed[2:0] | 1 | 2 | 4 |
|-----------------------|--------|--------|--------|
| min_line_blanking_pck | 0x02E1 | 0x01C9 | 0x013D |
| min_line_length_pck | 0x03E1 | 0x0370 | 0x02E0 |

In addition, enough time must be given to the output FIFO so it can output all data at the set frequency within one row time.

There are therefore three checks that must all be met when programming line_length_pck:

- line_length_pck \geq min_line_length_pck in Table 13.
- line_length_pck \ge (x_addr_end x_addr_start + x_odd_inc)/((1+x_odd_inc)/2) + min_line_blanking_pck in Table 13.
- The row time must allow the FIFO to output all data during each row. That is, line_length_pck ≥ (x_output_size / 2) * (vt_pix_clk_freq)/(op_pix_clk_freq)

Minimum Frame Time

The minimum number of rows in the image is 2, so min_frame_length_lines will always equal (min_frame_blanking_lines + 2).

Table 14: Minimum Frame Time and Blanking Numbers

| min_frame_blanking_lines | 0x0093 |
|--------------------------|--------|
| min_frame_length_lines | 0x054B |

Integration Time

The integration (exposure) time of the MT9D015 is controlled by the fine_integration_time and coarse_integration_time registers.

The limits for the fine integration time are defined by:

 $fine_integration_time_min < = fine_integration_time < = (line_length_pck-fine_integration_time_max_margin) \quad (EQ \ 9)$

The limits for the coarse integration time are defined by:

 $coarse_integration_time_min < = coarse_integration_i$ (EQ 10)

If coarse_integration_time > (frame_lenth_lines-coarse_integration_time_max_margin), then the frame rate will be reduced.

The actual integration time is given by:

$$integration_time [sec] = \frac{((coarse_integration_time*line_length_pck) + fine_integration_time)}{(vt_pix_clk_freq_mhz*1*10^{6})}$$
(EQ 11)

With a vt_pix_clk of 64 MHz, the maximum integration time that can be achieved without reducing the frame rate is given by:

$$Maximum integration time [sec] =$$
(EQ 12)

(((frame_length_lines -1) * line_length_pck) + (line_length_pck - fine_integration_time_max_margin) (vt_pix_clk_freq_mhz * 1* 10⁶)

$$= \frac{(((0x0503)*0x0938)+0x7A3)}{(64 \ MHz*1*10^{6})} = 47.34ms$$

Setting an integration time that is greater than the frame time increases the frame time beyond frame_length_lines to make longer exposure times available.

Fine Integration Time Limits

The limits for the fine_integration_time can be found from fine_integration_time_min and fine_integration_time_max_margin. Values for different mode combinations are shown in Table 15.

Table 15: fine_integration_time Limits

| row_speed[2:0] | 1 | 2 | 4 |
|----------------------------------|--------|--------|--------|
| fine_integration_time_min | 0x01E5 | 0x0104 | 0x0052 |
| fine_integration_time_max_margin | 0x0191 | 0x00B7 | 0x008B |

Analog Gain

The MT9D015 provides two mechanisms for setting the analog gain. The first uses the SMIA gain model; the second uses the traditional ON Semiconductor gain model. The following sections describe both models, the mapping between the models, and the operation of the per-color and global gain control.

Using Per-color or Global Gain Control

The read-only analogue_gain_capability register returns a value of "1," indicating that the MT9D015 provides per-color gain control. However, the MT9D015 also provides the option of global gain control. Per-color and global gain control can be used interchangeably. A write to a global gain register is aliased as a write of the same data to the four associated color-dependent gain registers. A read from a global gain register is aliased to a read of the associated greenB/greenR gain register.

The read/write gain mode register required by SMIA has no defined function in the SMIA specification. In the MT9D015 this register has no side effects on the operation of the gain; per-color and global gain control can be used interchangeably regardless of the state of the gain_mode register.

SMIA Gain Model

The SMIA gain model uses the following registers to set the analog gain:

- analogue_gain_code_global
- analogue_gain_code_greenR
- analogue_gain_code_red
- analogue_gain_code_blue
- analogue_gain_code_greenB

The SMIA gain model requires a uniform step size between all gain settings. The analog gain is given by:

$$gain = \frac{analogue_gain_m0 \ x \ analogue_gain_code}{analogue_gain_c1} = \frac{analogue_gain_code_}{8}$$
(EQ 13)

ON Semiconductor Gain Model

The ON Semiconductor gain model uses the following registers to set the analog gain:

- global_gain
- greenr_gain
- red_gain
- blue_gain
- greenb_gain

This gain model maps directly to the control settings applied to the gain stages of the analog signal chain. This provides a 7-bit gain stage and a number of 2X gain stages. As a result, the step size varies depending upon whether the 2X gain stages are enabled. The analog gain is given by:

$$gain = (\langle color \rangle_gain[8] + 1) \times (\langle color \rangle_gain[7] + 1) \times \frac{\langle color \rangle_gain[6:0]}{32}$$
(EQ 14)

As a result of the 2X gain stage, many of the possible gain settings can be achieved in two different ways. In all cases, the preferred setting is the setting that uses <*color>_gain[7]* first, <*color>_gain[6:0]*, and then <*color>_gain[8]* to apply the desired gain range,, because this will result in lower noise.

Gain Code Mapping

The ON Semiconductor gain model maps directly to the underlying structure of the gain stages in the analog signal chain. When the SMIA gain model is used, gain codes are translated into equivalent settings in the ON Semiconductor gain model.

When the SMIA gain model is in use and values have been written to the analogue_gain_code_<color> registers, the associated value in the ON Semiconductor gain model can be read from the associated <color>_gain register. In cases where there is more than one possible mapping, the 2X gain stage is enabled to provide the mapping with the lowest noise.

When the ON Semiconductor gain model is in use and values have been written to the gain_<color> registers, data read from the associated analogue_gain_code_<color> register is undefined. The reason for this is that many of the gain codes available in the ON Semiconductor gain model have no corresponding value in the SMIA gain model.

The result is that the two gain models can be used interchangeably, but having written gains through one set of registers, those gains should be read back through the same set of registers.

Minimum Gain and Gain Table

111

To make the sensor reach saturation status in high light condition, the gain value applied to this part must larger than 1.375X. In other words, the 1.375X is the minimum gain.

| 5MIA Gain (R0x0204) | Global Gain (R0x305E) | Gain | |
|---------------------|--------------------------|-------|--|
| 0x0008 | 0x1020 | 1 | |
| 0x0009 | 0x1024 | 1.125 | |
| A000x0 | 0x1028 | 1.25 | |
| 0x000B | 0x102C | 1.375 | |
| 0x000C | 0x1030 | 1.5 | |
| 0x000D | 0x1034 | 1.625 | |
| 0x000E | 0x1038 | 1.75 | |
| 0x000F | 0x103C | 1.875 | |
| 0x0010 | 0x10A0 | 2 | |
| 0x0011 | 0x10A2 | 2.125 | |
| 0x0012 | 0x10A4 | 2.25 | |
| 0x0013 | 0x10A6 | 2.375 | |
| 0x0014 | 0x10A8 | 2.5 | |
| 0x0015 | 0x10AA | 2.625 | |
| 0x0016 | 0x10AC | 2.75 | |

Table 16:Gain Table (continued)

Notes: 1. 1-1.25 gains have been grayed out. Customers should not use less than x1.375 gain to avoid un-saturation issue.

2. The gain range 1-7.875 used analog gain only. The range 8 - 15.875 used 2X digital gain. When R0x0204[6]= R0x305E[8]=1, 2X digital gain is enabled.

Sensor Core Digital Data Path

Test Patterns

The MT9D015 supports a number of test patterns to facilitate system debug. Test patterns are enabled using test_pattern_mode (R0x0600–1). The test patterns are listed in Table 17.

Table 17: Test Patterns

| test_pattern_mode | Description |
|-------------------|-----------------------------------|
| 0 | Normal operation: no test pattern |
| 1 | Solid color |
| 2 | 100% color bars |
| 3 | Fade-to-gray color bars |
| 4 | PN9 link integrity pattern |

Test patterns 0–3 replace pixel data in the output image (the embedded data rows are still present). Test pattern 4 replaces all data in the output image (the embedded data rows are omitted and test pattern data replaces the pixel data).

For all of the test patterns, the MT9D015 registers must be set appropriately to control the frame rate and output timing. These include:

- All clock divisors
- x_addr_start
- x_addr_end
- y_addr_start
- y_addr_end
- frame_length_lines
- line_length_pck
- x_output_size
- y_output_size

The MT9D015 will disable digital corrections automatically when test patterns are activated. The test cursor is now added to the end of the data path.

Solid Color Test Pattern

In this mode, all pixel data is replaced by fixed Bayer pattern test data. The intensity of each pixel is set by its associated test data register (test_data_red, test_data_greenR, test_data_blue, test_data_greenB).

100 Percent Color Bars Test Pattern

In this test pattern, shown in Figure 23 on page 56, all pixel data is replaced by a Bayer version of an 8-color, color-bar chart (white, yellow, cyan, green, magenta, red, blue, and black). Each bar is 200 pixels wide and occupies the full height of the output image. Each color component of each bar is set to either "0" (fully off) or 0x3FF (fully on for 10-bit data). The pattern repeats after 8 * 200 = 1600 pixels. The image size is set by x_ad-dr_start, x_addr_end, y_addr_start, y_addr_end and may be affected by the setting of x_output_size, y_output_size. The color-bar pattern starts at the column identified by x_addr_end - x_addr_start and the setting of x_output_size. The width of each color-bar is fixed at 200 pixels.

The effect of setting horizontal_mirror in conjunction with this test pattern is that the order in which the colors are generated is reversed. The black bar appears at the left side of the output image. Any pattern repeat occurs at the right side of the output image regardless of the setting of horizontal_mirror. The state of vertical_flip has no effect on this test pattern.

The effect of subsampling and scaling of this test pattern is undefined.

Figure 23: 100 Percent Color Bars Test Pattern

Horizontal mirror = 0

Horizontal mirror = 1

Fade-to-Gray Color Bars Test Pattern

In this test pattern, shown in Figure 24 on page 58, all pixel data is replaced by a Bayer version of an 8-color, color-bar chart (white, yellow, cyan, green, magenta, red, blue, and black). Each bar is 200 pixels wide and occupies 1024 rows of the output image. Each color bar fades vertically from full intensity at the top of the image to 50 percent intensity (mid-gray) on the 1024th row. Each color bar is divided into a left and a right half, in which the left half fades smoothly and the right half fades in quantized steps every 8 pixels for a given color. Due to the Bayer pattern of the colors this means that the level changes every 16 rows. The pattern repeats horizontally after 8 * 200 = 1600 pixels and vertically after 1024 rows (using 10-bit data, the fade-to-gray pattern goes from 100 to 50 percent or from 0 to 50 percent for each color component, so only half of the 2¹⁰ states of the 10-bit data are used. However, to get all of the gray levels, each state must be held for two rows, hence the vertical size of $2^{10} / 2 * 2 = 1024$). The image size is set by x_addr_start, x_addr_end, y_addr_start, and y_addr_end and may be affected by the setting of x_output_size and y_output_size. The color-bar pattern starts at the column identified by x_addr_start. The number of colors that are visible in the output is dependent upon x_addr_end - x_addr_start and the setting of x_output_size. The width of each color-bar is fixed at 200 pixels.

The effect of setting horizontal_mirror or vertical_flip in conjunction with this test pattern is that the order in which the colors are generated is reversed. The black bar appears at the left side of the output image. Any pattern repeat occurs at the right side of the output image regardless of the setting of horizontal_mirror.

The effect of subsampling and scaling of this test pattern is undefined.

Figure 24: Fade-to-Gray Color Bars Test Pattern

Horizontal mirror = 0, Vertical flip = 0

Horizontal mirror = 0, Vertical flip = 1

Horizontal mirror = 1, Vertical flip = 0

Horizontal mirror = 1, Vertical flip = 1

PN9 Link Integrity Pattern

This test pattern provides a 512-bit pseudo-random test sequence to test the integrity of the serial pixel data output stream. The polynomial $x^9 + x^5 + 1$ is used. The polynomial is initialized to 0x1FF at the start of each frame.

When this test pattern is enabled:

- The embedded data rows are disabled, and the value of frame_format_decriptor_1 changes from 0x1002 to 0x1000 to indicate that no rows of embedded data are present.
- The whole output frame, bounded by the limits programmed in x_output_size and y_output_size, is filled with data from the PN9 sequence.
- The output data format is (effectively) forced into RAW10 mode regardless of the state of the data_format register.

This polynomial generates the following sequence of 10-bit values: 0x1FF, 0x378, 0x1A1, 0x336, 0x385, and so on. On the serial pixel data output, these values are streamed out sequentially without performing the RAW10 packing to bytes that normally occurs on this interface.

Test Cursors

The MT9D015 supports one horizontal and one vertical cursor, allowing a "cross hair" to be superimposed on the image or on test patterns 1–3.

The position and width of each cursor are programmable in R0x31E8–0x31EE. Each cursor can be inhibited by setting its width to "0."

The programmed cursor position corresponds to an absolute row or column in the pixel array. For example, setting horizontal_cursor_position to the same value as y_addr_start would result in a horizontal cursor being drawn starting on the first row of the image.

The cursors are opaque (they replace data from the imaged scene or test pattern). The color of each cursor is set by the values of the Bayer components in the test_data_red, test_data_greenR, test_data_blue, and test_data_greenB registers. As a consequence, the cursors are the same color as test pattern 1 and are therefore invisible when test pattern 1 is selected.

When vertical_cursor_position = 0x0FFF, the vertical cursor operates in an automatic mode in which its position advances every frame. In this mode the cursor starts at the column associated with x_addr_start = 0 and advances by a step-size of 8 columns each frame until it reaches the column associated with x_addr_start = 2040, after which it wraps (256 steps). Note that the active pixel array is smaller than this, so in the last 56 steps the cursor will not be visible. The width and color of the cursor in this automatic mode are controlled in the usual way.

The effect of enabling the test cursors when the image_orientation register is non-zero is not defined by the SMIA specification. The behavior of the MT9D015 is shown in Figure 25 on page 60. In this figure the test cursors are shown as translucent for clarity. In practice, they are opaque (they overlay the imaged scene). The manner in which the test cursors are affected by the value of image_orientation can be understood from the following implementation details:

- The test cursors are inserted early in the data path, so that they correlate to rows and to columns of the physical pixel array (rather than to x and to y coordinates of the output image).
- The drawing of a cursor starts when the pixel array row or column address matches the value of the associated cursor_position register. As a result, the cursor start position remains fixed relative to the rows and columns of the pixel array for all settings of image_orientation.
- The cursor generation continues until the appropriate cursor_width pixels have been drawn. The cursor width is generated from the start position and proceeds in the direction of pixel array readout. As a result, each cursor is reflected about an axis corresponding to its start position when the appropriate bit is set in the image_orientation register.

Digital Gain

Integer digital gains in the range 1–7 can be programmed. A digital gain of "0" sets all pixel values to "0" (the pixel data will simply represent the value applied by the pedestal block).

Pedestal

This block adds the value from R0x0008-9 (data_pedestal_) to the incoming pixel value.

The data_pedestal register is read-only by default but can be made read/write by clearing the lock_reg bit in R0x301A–B.

The only way to disable the effect of the pedestal is to set it to "0."

Digital Data Path

The digital data path after the sensor core is shown in Figure 26.

Figure 26: Data Path

Timing Specifications

Power-Up Specifications

The digital and analog supply voltages can be powered up in any order. However, ON Semiconductor recommends the following power-up sequence to minimize current consumption. The power-up sequence corresponds to the requirements described in section 3.2 of the SMIA functional specification.

Power-Up Sequence

The recommended power-up sequence for the MT9D015 is shown in Figure 27 and Table 18 on page 63. The available power supplies—VDD, VDD_PLL, VAA, VAA_PIX—can be turned on at any point or have the separation specified below for reducing current consumption during power-up sequence.

- 1. Turn on the VDD power supply.
- 2. After 0–500ms, turn on VDD_PLL and VAA/VAA_PIX power supplies.
- 3. After the last power supply is stable, enable EXTCLK.
- 4. After EXTCLK is stable, assert RESET_BAR for at least 1ms.
- 5. Wait 1200 EXTCLKs for internal initialization into soft standby.
- 6. Configure PLL, output, and image settings to desired values.
- 7. Wait 16000 EXTCLKs for the PLL to lock before streaming state is reached (enforced in hardware).
- 8. Set mode_select = 1 (R0x0100) to start streaming.

Table 18: Power-Up Sequence

| Definition | Symbol | Min | Тур | Max | Unit |
|-------------------------|----------------|-------|-----|-----|---------|
| VDD to VDD_PLL time | ^t 1 | 0 | - | 500 | ms |
| VDD to VAA/VAA_PIX time | ^t 2 | 0 | _ | 500 | ms |
| Active hard reset | ^t 3 | 1 | _ | - | ms |
| Internal initialization | ^t 4 | 1200 | - | - | EXTCLKs |
| PLL lock time | ^t 5 | 16000 | _ | - | EXTCLKs |
| Soft Standby | ^t 6 | 500 | _ | | ms |
| Delay 1 | ^t 7 | 600 | - | | ms |
| Delay 2 | ^t 8 | 600 | _ | | ms |

Power-Down Specification

The digital and analog supply voltages can be powered down in any order. However, ON Semiconductor recommends the following power-down sequence to minimize current consumption. The power-down sequence corresponds to the requirements described in section 3.2 of the SMIA functional specification.

Power-Down Sequence

The recommended power-down sequence for the MT9D015 is shown in Figure 28 and in Table 19 on page 64. The available power supplies—VDD, VDD_PLL, VAA, VAA_PIX—can be turned off at any point or have the separation specified below for reducing current consumption during power-down sequence.

- 1. Disable streaming if output is active by setting mode_select = 0 (R0x0100).
- 2. The soft standby state is reached after the current row or frame, depending on configuration, has ended.
- 3. Assert hard reset by setting RESET_BAR to a logic "0" at least 1ms.
- 4. Stop EXTCLK; drive this pin to logic "0."
- 5. Turn off the VAA/VAA_PIX and VDD_PLL power supplies.
- 6. After 0–500ms, turn off VDD and power supply.

Figure 28: Power-Down Sequence

Table 19: Power-Down Sequence

| Definition | Symbol | Min | Тур | Max | Unit |
|-------------------------|----------------|-----|-----|-----|------|
| Hard reset | ^t 1 | 1 | - | - | ms |
| VAA/VAA_PIX to VDD time | ^t 2 | 0 | - | 500 | ms |
| VDD_PLL to VDD time | t3 | 0 | - | 500 | ms |

Hard Standby and Hard Reset

The hard standby state is reached by the assertion of the RESET_BAR pad (hard reset). Register values are not retained by this action, and will be returned to their default values once hard reset is completed. The minimum power consumption is achieved by the hard standby state. This operating mode complies with section 3.1 of the SMIA Functional Specification.

Soft Standby and Soft Reset

The MT9D015 can reduce power consumption by switching to the soft standby state when the output is not needed. Register values are retained in the soft standby state. Once this state is reached, soft reset can be optionally enabled to return all register values back to the default. The details of the sequence are shown in Figure 29.

Soft Standby

- 1. Disable streaming if output is active by setting mode_select = 0 (R0x0100).
- 2. The soft standby state is reached after the current row or frame, depending on configuration, has ended.

Soft Reset

1. Follow the soft standby sequence list.

- 2. Delay 1 frame time; set software_reset = 1 (R0x0103) to start the internal initialization sequence.
- 3. After 700 EXTCLKs, the internal initialization sequence is completed and the current state returns to soft standby automatically. All registers, including software_reset, returns to their default values.

Figure 29: Soft Standby and Soft Reset

Electrical Specifications

EXTCLK

The electrical characteristics of the EXTCLK input are shown in Table . The EXTCLK input supports an AC-coupled sine-wave input clock or a DC-coupled square-wave input clock.

Table 20: Electrical Characteristics (EXTCLK)

| Definition | Condition | Symbol | Min | Тур | Max | Unit |
|---|----------------|---------------------|------------|------|-----------|----------------|
| Input clock frequency | | f _{EXTCLK} | 6 | 16 | 27 | MHz |

| Rise time (20–80%) | | 300 | | 400 | ps |
| Fall time (20–80%) | | 300 | | 400 | ps |
| Differential skew | | | | 500 | ps |
| Channel-to-channel slew | | | | 200 | ps |
| Maximum data rate Data/strobe mode Data/clock mode | | | | 640 208 | Mb/s |
| Power supply rejection ratio (PSRR) 0–100 MHz | | 30 | | | dB |
| Power supply rejection ratio (PSRR) 100–1000 MHz | | 10 | | | dB |

Table 24: Electrical Characteristics (Serial MIPI Pixel Data Interface)

VDD = 1.8V; VAA = 2.8V; VAA_PIX = 2.8V; VVDD_PLL = 2.8V; Ambient temperature

| Definition | Symbol | Min | Тур | Max | Unit |
|---|----------------|-----|-----|-----|------|
| High speed transmit differential voltage | Vod | 140 | | 270 | mV |
| High speed transmit static common-mode voltage | Vсмтх | 150 | | 250 | mV |
| Vod mismatch when output is Differential-1 or Differential-0 | dVod | | | <14 | mV |
| High speed output high voltage mismatch | dVCMTX | | | 16 | mV |
| Single ended output impedance | Zos | 40 | | 64 | Ω |
| Single ended output impedance mismatch | dZos | | | 10 | % |
| 20–80% rise time | ^t R | | | 250 | ps |
| 20–80% fall time | ^t F | | | 250 | ps |
| Output LOW level | Vol | | | 50 | mV |
| Output HIGH level | Voн | | | 1.3 | V |
| Output impedance of low power parameter | Zolp | | | 110 | Ω |
| 15–85% rise time | Trlp | | | 25 | ns |
| 15–85% fall time | TFLP | | | 25 | ns |

Table 24: Electrical Characteristics (Serial MIPI Pixel Data Interface)

VDD = 1.8V; VAA = 2.8V; VAA_PIX = 2.8V; VVDD_PLL = 2.8V; Ambient temperature

| Definition | Symbol | Min | Тур | Max | Unit |
|---|---------|-----|-----|-----|-------|
| Slew rate (CLOAD = 5–20pF) | dv/dtsr | | | 235 | mV/ns |
| Slew rate (CLOAD = 20–70pF) | dv/dstr | | | 200 | mV/ns |
| Power supply rejection ratio (PSRR) 0–100 MHz | | 30 | | | dB |
| Power supply rejection ratio (PSRR) 100–1000 MHz | | 10 | | | dB |

Control Interface

The electrical characteristics of the control interface (RESET_BAR, TEST, GPI0, GPI1, GPI2, and GPI3) are shown in Table 25.

Table 25:Electrical Characteristics

| Definition | Condition | Symbol | Min | Тур | Max | Unit |
|-----------------------|---|--------|-----------|-----|-----------|------|
| Input HIGH voltage | | Viн | 0.7 x VDD | | 2.9 | V |
| Input LOW voltage | | VIL | -0.3 | | 0.3 x VDD | V |
| Input leakage current | No pull-up resistor; VIN = VDD or DGND | lin | | | 10 | μA |
| Input pad capacitance | | Cin | | 6.5 | | pF |

Power-On Reset

Table 26: Power-On Reset Characteristics

| Definition | Condition | Symbol | Min | Тур | Max | Unit |
|--|--|----------------|------|-----|------|------|
| VDD rising, crossing VTRIG_RISING; Internal reset being released | | ^t 1 | 7 | 10 | 15 | μs |
| VDD falling, crossing VTRIG_FALLING; Internal reset active | | ^t 2 | | 0.5 | 1 | μs |
| Minimum VDD spike width below VTRIG_FALLING; considered to be a reset when POR cell output is HIGH | | ^t 3 | | 0.5 | | μs |
| Minimum VDD spike width below VTRIG_FALLING; considered to be a reset when POR cell output is LOW | | ^t 4 | | 1 | | μs |
| Minimum VDD spike width above VTRIG_RISING; considered to be a stable supply when POR cell output is LOW | While the POR cell output is LOW, all VDD spikes above VTRIG_RISING less than ^t 5 must be ignored | ^t 5 | | 50 | | ns |
| VDD rising trigger voltage | | VTRIG_RISING | 1.15 | | 1.55 | V |
| VDD falling trigger voltage | | VTRIG_FALLING | 1 | | 1.45 | V |

Figure 31: Internal Power-On Reset

Operating Voltages

VAA and VAA_PIX must be at the same potential for correct operation of the MT9D015.

Table 27:DC Electrical Definitions and Characteristics

Setup Conditions: TJ = 25°C; Dark lighting conditions

| Definition | Condition | Symbol | Min | Тур | Max | Unit |
|--------------------------------|---------------------|---------|-----|-----|-----|------|
| Core digital voltage | | Vdd | 1.7 | 1.8 | 1.9 | V |
| Analog voltage | | VAA | 2.4 | 2.8 | 2.9 | V |
| Pixel supply voltage | | VAA_PIX | 2.4 | 2.8 | 2.9 | V |
| PLL supply voltage | | VDD_PLL | 2.4 | 2.8 | 2.9 | V |
| Digital operating current | 1600x1200 at 30 fps | IDIG | 10 | 50 | 71 | mA |
| Analog operating current | | IANA | 25 | 65 | 80 | mA |
| Digital operating current | 1600x1200 at 15fps | IDIG | | 25 | 30 | mA |
| Analog operating current | | IANA | | 52 | 58 | mA |
| Digital operating current | 1280x720 at30 fps | IDIG | | 48 | 55 | mA |
| Analog operating current | Full field of view | IANA | | 65 | 73 | mA |
| Digital operating current | 640x480 at 30 fps | IDIG | | 24 | 30 | mA |
| Analog operating current | | IANA | | 40 | 45 | mA |
| Digital operating current | 320x240 at 120 fps | IDIG | | 30 | 35 | mA |
| Analog operating current | | IANA | | 49 | 55 | mA |
| Hard standby | Analog | | | | 10 | uA |
| | Digital | | | | 15 | uA |
| Soft standby (clock off) | Analog | | | 20 | 275 | uA |
| | Digital | | | 30 | 300 | uA |
| Soft standby (clock on 6 MHz) | Analog | | | 20 | 275 | uA |
| | Digital | | | 50 | 500 | uA |
| Soft standby (clock on 27 MHz) | Analog | | | 20 | 275 | uA |
| | Digital | | | 1 | 3 | mA |

Absolute Maximum Ratings

Caution Stresses greater than those listed in Table 28 may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Table 28: Absolute Maximum Values

| Definition | Condition | Symbol | Min | Max | Unit |
|-----------------------|---------------------|-------------|-----------|-----------|------|
| Core digital voltage | | VDD_MAX | -0.3 | 2.2 | V |
| Analog voltage | | VAA_MAX | -0.3 | 3.2 | V |
| Pixel supply voltage | | VAA_PIX_MAX | -0.3 | 3.2 | V |
| PLL supply voltage | | VDD_PLL_MAX | -0.3 | 3.2 | V |
| Input HIGH voltage | | VIH_MAX | 0.7 x Vdd | VAA + 0.3 | V |
| Input LOW voltage | | VIH_MAX | -0.3 | 0.3 x VDD | V |
| Operating temperature | Measure at junction | Тор | -30 | 70 | °C |
| Storage temperature | | Тѕтд | -40 | 125 | °C |

Note:

This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

Chief Ray Angle

| | Image | Height | CRA |

SMIA and MIPI Specification Reference

The sensor design and this documentation is based on the following reference documents:

- SMIA Specifications:
 - Functional Specification:
 SMIA 1.0 Part 1: Functional Specification (Version 1.0 dated 30 June 2004)
 SMIA 1.0 Part 1: Functional Specification ECR0001 (Version 1.0 dated 11 Feb 2005)
 - Electrical Specification:
 SMIA 1.0 Part 2: CCP2 Specification (Version 1.0 dated 30 June 2004)
 SMIA 1.0 Part 2: CCP2 Specification ECR0001 (Version 1.0 dated 11 Feb 2005)
- MIPI Specifications:
 - MIPI Alliance Standard for CSI-2 version 1.0
 - MIPI Alliance Standard for D-PHY version 1.0

Revision History

| Rev. M | |
|--------|--|
| • | Updated "Ordering Information" on page 2 |
| | |
| | |
| | Updated to ON Semiconductor template |
| • | Removed Confidential marking |
| Rev. K | |
| • | Updated Figure 27: "Power-Up Sequence," on page 62 |
| • | Updated Table 18, "Power-Up Sequence," on page 63 |
| D I | 1/04/10 |
| Rev. J | Updated Table 27, "DC Electrical Definitions and Characteristics," on page 71 |
| Rev H | |
| | Updated "Minimum Gain and Gain Table" on page 52 |
| | Updated Table 16, "Gain Table," on page 52 |
| | Updated Table 20, "Electrical Characteristics (EXTCLK)," on page 66 |
| | Updated "Two-Wire Serial Register Interface" on page 66 |
| | Updated Table 26, "Power-On Reset Characteristics," on page 69 |
| | |
| Rev.G | |
| | Updated "Features" on page 1 |
| | Updated Table 1, "Key Performance Parameters," on page 1 |
| • | Updated Note 7 and added Note 8 in Figure 3: "Typical Configuration (Connection) – |
| | Serial Output Mode," on page 8 and in Figure 4: "Typical Configuration (Connection) – MIPI Mode," on page 9 |
| • | Updated Table 6, "Embedded Data," on page 19 |
| | Updated Table 11, "Streaming/STANDBY," on page 36 |
| | Updated "Profile 0 Behavior" on page 37 |
| | Added "One-Time Programmable Memory (OTPM)" on page 41 |
| | Added "Full Resolution Frame Structure With Embedded Data" on page 43 |
| | Added Note to "Frame Rate Control" on page 48 |
| | Added "Minimum Row Time" on page 48 |
| | Added "Minimum Frame Time" on page 48 |
| | Added "Fine Integration Time Limits" on page 49 |
| • | Added "Minimum Gain and Gain Table" on page 52 |
| • | Updated Table 23, "Electrical Characteristics (Serial CCP2 Pixel Data Interface)," on |
| | page 68 |
| • | Updated Table 24, "Electrical Characteristics (Serial MIPI Pixel Data Interface)," on |
| | page 68 |
| • | Updated Figure 31: "Internal Power-On Reset," on page 70 |
| • | Updated Table 27, "DC Electrical Definitions and Characteristics," on page 71 |
| • | Updated "SMIA and MIPI Specification Reference" on page 73 |
| Rev. F | |
| | Added information for MIPI functionality |
| • | |

• Added "Chief Ray Angle" on page 72

| Rev. E | Added maximum values for digital operating current and analog operating current in |
|---------------------|---|
| | Table 22, "DC Electrical Definitions and Characteristics," on page 62 |
| • | Updated Figure 28: "Power-Down Sequence," on page 64 |
| Rev. D, Production | |
| • | Updated to Production |
| • | Applied updated Aptina template |
| • | Updated Table 1, "Key Performance Parameters," on page 1 |
| Rev. C, Preliminary | |
| • | Updated Table 20, "Electrical Characteristics (EXTCLK)," on page 66 |
| • | Updated Table 21, "Two-Wire Serial Register Interface Electrical Characteristics," on page 65 |
| • | Updated Table 23, "Electrical Characteristics (Serial CCP2 Pixel Data Interface)," on page 68 |
| • | Updated Table 25, "Electrical Characteristics," on page 69 |
| • | Updated Table 26, "Power-On Reset Characteristics," on page 69 |
| • | Updated Table 22, "DC Electrical Definitions and Characteristics," on page 62 |
| • | Updated Table 28, "Absolute Maximum Values," on page 72 |
| Rev. B | |
| • | Updated "Effect of CCP2 Class on Legal Range of Output Sizes/Frame Rate" on page 30 |
| • | Updated Figure 13: "MT9D015 System States," on page 34 |
| • | Updated Table 9, "PLL in System States," on page 35 |
| • | Updated "Power-On Reset Sequence" on page 35 |
| • | Updated "General Purpose Inputs" on page 36 |
| • | Updated Figure 14: "MT9D015 SMIA Profile 1/2 Clocking Structure," on page 38 |
| • | Updated Figure 15: "MT9D015 SMIA Profile 0 Clocking Structure," on page 39 |
| • | Updated Equation 12 on page 49 |
| • | Updated "Power-Up Sequence" on page 62 |
| • | Updated Table 18, "Power-Up Sequence," on page 63 |
| • | Updated Figure 29: "Soft Standby and Soft Reset," on page 65 |
| • | Deleted note from Table 16, "Electrical Characteristics (EXTCLK)," on page 59 |
| | |

Мы молодая и активно развивающаяся компания в области поставок электронных компонентов. Мы поставляем электронные компоненты отечественного и импортного производства напрямую от производителей и с крупнейших складов мира.

Благодаря сотрудничеству с мировыми поставщиками мы осуществляем комплексные и плановые поставки широчайшего спектра электронных компонентов.

Собственная эффективная логистика и склад в обеспечивает надежную поставку продукции в точно указанные сроки по всей России.

Мы осуществляем техническую поддержку нашим клиентам и предпродажную проверку качества продукции. На все поставляемые продукты мы предоставляем гарантию.

Осуществляем поставки продукции под контролем ВП МО РФ на предприятия военно-промышленного комплекса России, а также работаем в рамках 275 ФЗ с открытием отдельных счетов в уполномоченном банке. Система менеджмента качества компании соответствует требованиям ГОСТ ISO 9001.

Минимальные сроки поставки, гибкие цены, неограниченный ассортимент и индивидуальный подход к клиентам являются основой для выстраивания долгосрочного и эффективного сотрудничества с предприятиями радиоэлектронной промышленности, предприятиями ВПК и научноисследовательскими институтами России.

С нами вы становитесь еще успешнее!
