

## Ultra Low Power, Rail-to-Rail Output, Fully-Differential Amplifier

Check for Samples: [THS4531A](#)

### FEATURES

- **Ultra Low Power:**
  - Voltage: 2.5 V to 5.5 V
  - Current: 250  $\mu$ A
  - Power-Down Mode: 0.5  $\mu$ A (typ)
- **Fully-Differential Architecture**
- **Bandwidth: 36 MHz**
- **Slew Rate: 200 V/ $\mu$ s**
- **THD: –120 dBc at 1 kHz (1  $V_{RMS}$ ,  $R_L = 2$  k $\Omega$ )**
- **Input Voltage Noise: 10 nV/ $\sqrt{Hz}$  ( $f = 1$  kHz)**
- **High DC Accuracy:**
  - $V_{OS}$ :  $\pm 100$   $\mu$ V
  - $V_{OS}$  Drift:  $\pm 3$   $\mu$ V/ $^{\circ}$ C (–40 $^{\circ}$ C to +125 $^{\circ}$ C)
  - $A_{OL}$ : 114 dB
- **Rail-to-Rail Output (RRO)**
- **Negative Rail Input (NRI)**
- **Output Common-Mode Control**

### APPLICATIONS

- **Low-Power SAR,  $\Delta\Sigma$  ADC Driver**
- **Low Power, High Performance:**
  - Differential to Differential Amplifier
  - Single-Ended to Differential Amplifier
- **Low-Power, Wide-Bandwidth Differential Driver**
- **Low-Power, Wide-Bandwidth Differential Signal Conditioning**
- **High Channel Count and Power Dense Systems**

### DESCRIPTION

The THS4531A is a low-power, fully-differential op amp with input common-mode range below the negative rail and rail-to-rail output. The device is designed for low-power data acquisition systems and high density applications where power consumption and dissipation is critical.

The device features accurate output common-mode control that allows for dc coupling when driving analog-to-digital converters (ADCs). This control, coupled with the input common-mode range below the negative rail and rail-to-rail output, allows for easy interface from single-ended ground-referenced signal sources to successive-approximation registers (SARs), and delta-sigma ( $\Delta\Sigma$ ) ADCs using only single-supply 2.5-V to 5-V power. The THS4531A is also a valuable tool for general-purpose, low-power differential signal conditioning applications.

The THS4531A is characterized for operation over the extended industrial temperature range from –40 $^{\circ}$ C to +125 $^{\circ}$ C. The following package options are available:

- 8-pin SOIC (MSOP) and VSSOP (D and DGK)
- 10-pin WQFN (RUN)

SLOS823A –DECEMBER 2012–REVISED JANUARY 2013

[www.ti.com](http://www.ti.com)

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

APPLICATION INFORMATION

TYPICAL CHARACTERISTICS TEST CIRCUITS

Figure 68 shows the general test circuit built on the EVM that was used for testing the THS4531A. For simplicity, power supply decoupling is not shown – please see layout in the applications section for recommendations. Depending on the test conditions, component values are changed per Table 2 and Table 3, or as otherwise noted. Some of the signal generators used are ac coupled 50Ω sources and a 0.22μF cap and 49.9Ω resistor to ground are inserted across R<sub>IT</sub> on the un-driven or alternate input as shown to balance the circuit. Split-power supply is used to ease the interface to common lab test equipment, but if properly biased, the amplifier can be operated single-supply as described in the applications section with no impact on performance. For most of the tests, the devices are tested with single ended input and a transformer on the output to convert the differential output to single ended because common lab test equipment have single ended inputs and outputs. Performance is the same or better with differential input and differential output.

Figure 68. General Test Circuit

Table 2. Gain Component Values for Single-Ended Input<sup>(1)</sup>

GAIN	R <sub>F</sub>	R <sub>G</sub>	R <sub>IT</sub>
1 V/V	2kΩ	2kΩ	51.1Ω
2 V/V	2kΩ	1kΩ	52.3Ω
5 V/V	2kΩ	392Ω	53.6Ω
10 V/V	2kΩ	187kΩ	57.6Ω

(1) Note components are chosen to achieve gain and 50Ω input termination. Resistor values shown are closest standard values so gains are approximate.

Table 3. Load Component Values For 1:1 Differential to Single-Ended Output Transformer<sup>(1)</sup>

R <sub>L</sub>	R <sub>O</sub>	R <sub>OT</sub>	ATTEN
100Ω	25Ω	open	6
200Ω	86.6Ω	69.8Ω	16.8
499Ω	237Ω	56.2Ω	25.5
1kΩ	487Ω	52.3Ω	31.8
2kΩ	976Ω	51.1Ω	37.9

(1) Note the total load includes 50Ω termination by the test equipment. Components are chosen to achieve load and 50Ω line termination through a 1:1 transformer. Resistor values shown are closest standard values so loads are approximate.

Due to the voltage divider on the output formed by the load component values, the amplifier's output is attenuated. The column "Atten" in [Table 3](#) shows the attenuation expected from the resistor divider. When using a transformer at the output as shown in [Figure 68](#), the signal will see slightly more loss due to transformer and line loss, and these numbers will be approximate. The standard output load used for most tests is 2k $\Omega$  with associated 37.9dB of loss.

### Frequency Response, and Output Impedance

The circuit shown in [Figure 68](#) is used to measure the frequency response of the amplifier.

A network analyzer is used as the signal source and the measurement device. The output impedance of the network analyzer is 50 $\Omega$  and is DC coupled.  $R_{IT}$  and  $R_G$  are chosen to impedance match to 50 $\Omega$  and maintain the proper gain. To balance the amplifier, a 49.9 $\Omega$  resistor to ground is inserted across  $R_{IT}$  on the alternate input.

The output is routed to the input of the network analyzer via 50 $\Omega$  coax. For 2k load, 37.9dB is added to the measurement to refer back to the amplifier's output per [Table 3](#).

For output impedance, the signal is injected at  $V_{OUT}$  with  $V_{IN}$  left open. The voltage drop across the 2x  $R_O$  resistors is measured with a high impedance differential probe and used to calculate the impedance seen looking into the amplifier's output.

### Distortion

At 1MHz and above, the circuit shown in [Figure 68](#) is used to measure harmonic, intermodulation distortion, and output impedance of the amplifier.

A signal generator is used as the signal source and the output is measured with a spectrum analyzer. The output impedance of the signal generator is 50 $\Omega$  and is AC coupled.  $R_{IT}$  and  $R_G$  are chosen to impedance match to 50 $\Omega$  and maintain the proper gain. To balance the amplifier, a 0.22 $\mu$ F cap and 49.9 $\Omega$  resistor to ground is inserted across  $R_{IT}$  on the alternate input. A low-pass filter is inserted in series with the input to reduce harmonics generated at the signal source. The level of the fundamental is measured and then a high-pass filter is inserted at the output to reduce the fundamental so it does not generate distortion in the input of the spectrum analyzer.

Distortion in the audio band is measured using an audio analyzer. Refer to audio measurement section for detail.

### Slew Rate, Transient Response, Settling Time, Overdrive, Output Voltage, and Turn-On/Off Time

The circuit shown in [Figure 69](#) is used to measure slew rate, transient response, settling time, overdrive recovery, and output voltage swing. Turn on and turn off times are measured with 50 $\Omega$  input termination on the  $\overline{PD}$  input, by replacing the 0.22 $\mu$ F capacitor with 49.9 $\Omega$  resistor.

Figure 69. Slew Rate, Transient Response, Settling Time,  $Z_o$ , Overdrive Recovery,  $V_{OUT}$  Swing, and Turn-on/off Test Circuit

### Common-Mode and Power Supply Rejection

The circuit shown in Figure 70 is used to measure the CMRR. The signal from the network analyzer is applied common-mode to the input.

Figure 70. CMRR Test Circuit

Figure 71 is used to measure the PSRR of  $V_{S+}$  and  $V_{S-}$ . The power supply is applied to the network analyzer's DC offset input. For both CMRR and PSRR, the output is probed using a high impedance differential probe across  $R_{OT}$ .

**Figure 71. PSRR Test Circuit**

**V<sub>OCM</sub> Input**

The circuit shown in [Figure 72](#) is used to measure the transient response, frequency response and input impedance of the V<sub>OCM</sub> input. For these tests, the cal point is across the 49.9Ω V<sub>OCM</sub> termination resistor. Transient response and frequency response are measured with R<sub>CM</sub> = 0Ω and using a high impedance differential probe at the summing junction of the two R<sub>O</sub> resistors, with respect to ground. The input impedance is measured using a high impedance differential probe at the V<sub>OCM</sub> pin and the drop across R<sub>CM</sub> is used to calculate the impedance seen looking into the amplifier's V<sub>OCM</sub> input.

**Figure 72. V<sub>OCM</sub> Input Test Circuit**

### Balance Error

The circuit shown in Figure 73 is used to measure the balance error of the main differential amplifier. A network analyzer is used as the signal source and the measurement device. The output impedance of the network analyzer is  $50\Omega$  and is DC coupled.  $R_{IT}$  and  $R_G$  are chosen to impedance match to  $50\Omega$  and maintain the proper gain. To balance the amplifier, a  $49.9\Omega$  resistor to ground is inserted across  $R_{IT}$  on the alternate input. The output is measured using a high impedance differential probe at the summing junction of the two  $R_O$  resistors, with respect to ground.

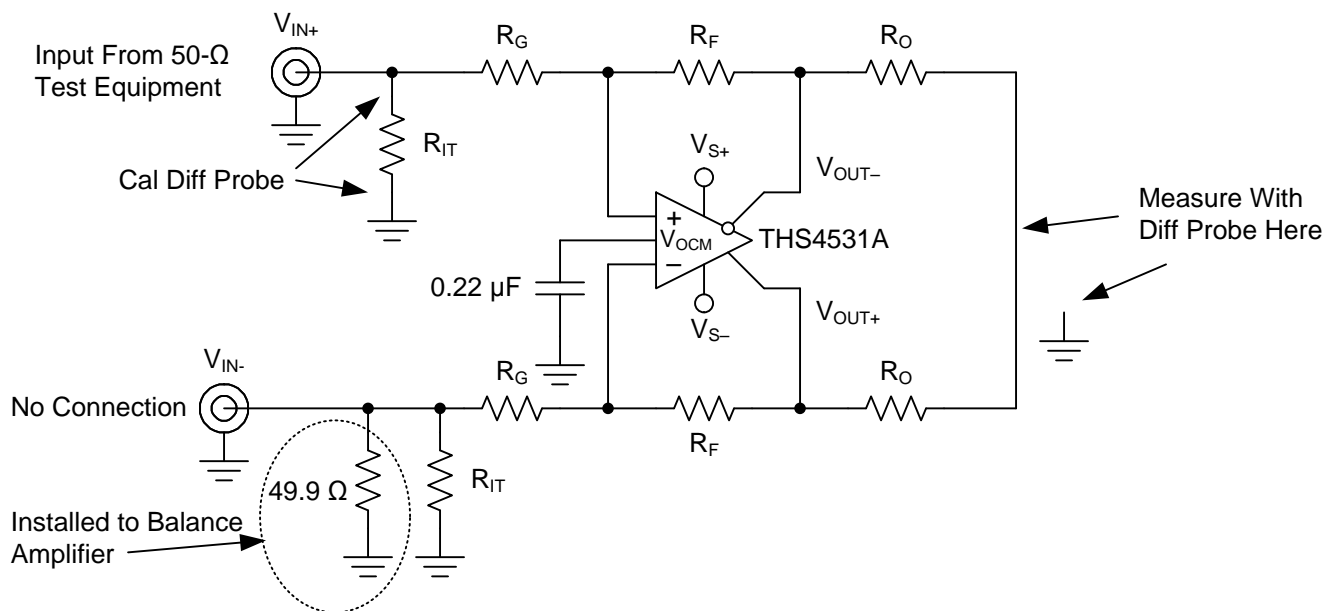

Figure 73. Balance Error Test Circuit

## APPLICATION CIRCUITS

The following circuits show application information for the THS4531A. For simplicity, power supply decoupling capacitors are not shown in these diagrams – please see the EVM and Layout Recommendations section for recommendations. For more detail on the use and operation of fully differential op amps refer to application report “Fully-Differential Amplifiers” [SLOA054D](#).

### Differential Input to Differential Output Amplifier

The THS4531A is a fully differential op amp and can be used to amplify differential input signals to differential output signals. A basic block diagram of the circuit is shown in [Figure 74](#) ( $V_{OCM}$  and PD inputs not shown). The gain of the circuit is set by  $R_F$  divided by  $R_G$ .

**Figure 74. Differential Input to Differential Output Amplifier**

### Single-Ended Input to Differential Output Amplifier

The THS4531A can also be used to amplify and convert single-ended input signals to differential output signals. A basic block diagram of the circuit is shown in [Figure 75](#) ( $V_{OCM}$  and PD inputs not shown). The gain of the circuit is again set by  $R_F$  divided by  $R_G$ .

**Figure 75. Single-Ended Input to Differential Output Amplifier**

### Differential Input to Single-Ended Output Amplifier

Fully differential op amps like the THS4531A are not recommended for differential to single-ended conversion. This application is best performed with an instrumentation amplifier or with a standard op amp configured as a classic differential amplifier. See application section of the OPA835 data sheet ([SLOS713](#)).

### Input Common-Mode Voltage Range

The input common-mode voltage of a fully differential op amp is the voltage at the “+ and –” input pins of the op amp.

It is important to not violate the input common-mode voltage range ( $V_{ICR}$ ) of the op amp. Assuming the op amp is in linear operation the voltage across the input pins is only a few millivolts at most. So finding the voltage at one input pin will determine the input common-mode voltage of the op amp.

Treating the negative input as a summing node, the voltage is given by:

$$\left( V_{OUT+} \times \frac{R_G}{R_G + R_F} \right) + \left( V_{IN-} \times \frac{R_F}{R_G + R_F} \right) \quad (1)$$

To determine the  $V_{ICR}$  of the op amp, the voltage at the negative input is evaluated at the extremes of  $V_{OUT+}$ .

As the gain of the op amp increases, the input common-mode voltage becomes closer and closer to the input common-mode voltage of the source.

### Setting the Output Common-Mode Voltage

The output common-mode voltage is set by the voltage at the  $V_{OCM}$  pin and the internal circuit works to maintain the output common-mode voltage as close as possible to this voltage. If left unconnected, the output common-mode is set to mid-supply by internal circuitry, which may be over-driven from an external source. Figure 76 is representative of the  $V_{OCM}$  input. The internal  $V_{OCM}$  circuit has about 24MHz of -3dB bandwidth, which is required for best performance, but it is intended to be a DC bias input pin. Bypass capacitors are recommended on this pin to reduce noise. The external current required to overdrive the internal resistor divider is given approximately by the formula:

$$I_{EXT} = \frac{2V_{OCM} - (V_{S+} - V_{S-})}{60k\Omega} \quad (2)$$

where  $V_{OCM}$  is the voltage applied to the  $V_{OCM}$  pin.

Figure 76. Simplified  $V_{OCM}$  Input Circuit

## Power Down

The power down pin is internally connected to a CMOS stage which must be driven to a minimum of 2.1V to ensure proper high logic.

**Figure 77. Simplified Power Down Internal Circuit**

If 1.8V logic is used to drive the pin, a shoot through current of up to 100μA may develop in the digital logic causing the overall quiescent current to exceed the 2μA of maximum disabled quiescent current specified in the electrical characteristics.

In order to properly interface to 1.8V logic with minimal increase in additional current draw, a logic-level translator like the SN74AVC1T45 can be used.

Alternatively, the same function may be achieved using a diode and pull up resistor shown below.

**Figure 78. THS4531A Power Down Interface to 1.8V Logic Microcontroller**

The voltage seen at the power down pin will be a function of the supply voltage, input logic level, and diode drop. As long as the diode is forward biased, the power down voltage will be determined by:

$$V_{PD} = V_L + V_f \quad (3)$$

Where  $V_L$  is the logic level voltage and  $V_f$  is the forward voltage drop across the diode.

This means for 1.8V logic, the forward voltage of the diode should be greater than 0.3V but less than 0.7V in order to keep the power down logic level above 2.1V and less than 0.7V respectively.

For example, if we select 1N914 as the diode with a forward voltage of approximately 0.4V, the translated logic voltages will be 0.4V for disabled operation and 2.2V for enabled operation.

The additional current draw can be determined by:

$$i_{PD} = \frac{V_{CC} - (V_L + V_f)}{R_{PU}} \quad (4)$$

This equation shows that larger values of  $R_{PU}$  result in a smaller additional current. A reasonable value of  $R_{PU}$  may be 500kΩ where we can expect to see an additional current draw of 5.2μA while the device is in operation and 1.6μA when disabled.

### Single-Supply Operation

To facilitate testing with common lab equipment, the THS4531A EVM is built to allow for split-supply operation and most of the data presented in this data sheet was taken with split-supply power inputs. But the device is designed for use with single-supply power operation and can easily be used with single-supply power without degrading the performance. The only requirement is to bias the device properly and the specifications in this data sheet are given for single supply operation.

### Low Power Applications and the Effects of Resistor Values on Bandwidth

The THS4531A is designed for the nominal value of  $R_F$  to be 2 k $\Omega$ . This gives excellent distortion performance, maximum bandwidth, best flatness, and best pulse response. It also loads the amplifier. For example; in gain of 1 with  $R_F = R_G = 2$  k $\Omega$ ,  $R_G$  to ground, and  $V_{OUT+} = 4$ V, 1mA of current will flow through the feedback path to ground. In low power applications, it is desirable to reduce this current by increasing the gain setting resistors values. Using larger value gain resistors has two primary side effects (other than lower power) due to their interaction with the device and PCB parasitic capacitance:

1. Lowers the bandwidth.
2. Lowers the phase margin
  - (a) This will cause peaking in the frequency response.
  - (b) And will cause over shoot and ringing in the pulse response.

Figure 79 shows the small signal frequency response for gain of 1 with  $R_F$  and  $R_G$  equal to 2k $\Omega$ , 10k $\Omega$ , and 100k $\Omega$ . The test was done with  $R_L = 2$ k $\Omega$ . Due to loading effects of  $R_L$ , lower values may reduce the peaking, but higher values will not have a significant effect.

As expected, larger value gain resistors cause lower bandwidth and peaking in the response (peaking in frequency response is synonymous with overshoot and ringing in pulse response).

**Figure 79. THS4531A Frequency Response with Various Gain Setting Resistor Values**

### Driving Capacitive Loads

The THS4531A is designed for a nominal capacitive load of 2pF (differentially). When driving capacitive loads greater than this, it is recommended to use small resistors ( $R_O$ ) in series with the output as close to the device as possible. Without  $R_O$ , capacitance on the output will interact with the output impedance of the amplifier causing phase shift in the loop gain of the amplifier that will reduce the phase margin resulting in:

1. Peaking in the frequency response.
2. Overshoot, undershoot, and ringing in the time domain response with a pulse or square-wave signal.
3. May lead to instability or oscillation.

Inserting  $R_O$  will compensate the phase shift and restore the phase margin, but it will also limit bandwidth. The circuit shown in Figure 69 is used to test for best  $R_O$  versus capacitive loads,  $C_L$ , with a capacitance placed differential across the  $V_{OUT+}$  and  $V_{OUT-}$  along with 2k $\Omega$  load resistor, and the output is measure with a differential probe. Figure 80 shows the optimum values of  $R_O$  versus capacitive loads,  $C_L$ , and Figure 81 shows the frequency response with various values. Performance is the same on both 2.7V and 5V supply.

Figure 80. Recommended Series Output Resistor vs Capacitive Load for Flat Frequency Response

Figure 81. Frequency Response for Various  $R_O$  and  $C_L$  Values

**Audio Performance**

The THS4531A provides excellent audio performance with very low quiescent power. To show performance in the audio band, the device was tested with an audio analyzer. THD+N and FFT tests were run at 1V<sub>rms</sub> output voltage. Performance is the same on both 2.7V and 5V supply. Figure 82 is the test circuit used, and Figure 83 and Figure 84 show performance of the analyzer. In the FFT plot the harmonic spurs are at the testing limit of the analyzer, which means the THS4531A is actually much better than can be directly measured. Because the THS4531A distortion performance cannot be directly measured in the audio band it is estimated from measurement in high noise gain configuration correlated with simulation.

Figure 82. THS4531A Audio Analyzer Test Circuit

Figure 83. THD+N on Audio Analyzer, 10 Hz to 24 kHz

Figure 84. 1kHz FFT Plot on Audio Analyzer

### Audio On/Off Pop Performance

The THS4531A is tested to show on and off pop performance by connecting a speaker between the differential outputs and switching on and off the power supply, and also by using the power down function of the THS4531A. Testing was done with and without tones. During these tests no audible pop could be heard.

With no input tone, [Figure 85](#) shows the voltage waveforms when switching power on to the THS4531A and [Figure 86](#) shows voltage waveforms when turning power off. The transients during power on and off show no audible pop should be heard.

**Figure 85. Power Supply Turn On Pop Performance**

**Figure 86. Power Supply Turn Off Pop Performance**

With no input tone, [Figure 87](#) shows the voltage waveforms using the  $\overline{\text{PD}}$  pin to enable and disable the THS4531A. The transients during power on and off show no audible pop should be heard.

Figure 87. PD Enable Pop Performance

### AUDIO ADC DRIVER PERFORMANCE: THS4531A AND PCM4204 COMBINED PERFORMANCE

To show achievable performance with a high performance audio ADC, the THS4531A is tested as the drive amplifier for the PCM4204. The PCM4204 is a high-performance, four-channel analog-to-digital (A/D) converter designed for professional and broadcast audio applications. The PCM4204 architecture utilizes a 1-bit delta-sigma modulator per channel incorporating an advanced dither scheme for improved dynamic performance, and supports PCM output data. The PCM4204 provides flexible serial port interface and many other advanced features. Please refer to its data sheet for more information.

The PCM4204 EVM is used to test the audio performance of the THS4531A as a drive amplifier. The standard PCM4204 EVM is provided with 4x OPA1632 fully differential amplifiers, which use the same pin out as the THS4531A. For testing, one of these amplifiers is replaced with a THS4531A device in same package (MSOP), gain changed to 1V/V, and power supply changed to single supply +5V. Figure 88 shows the circuit. With single supply +5V supply the output common-mode of the THS4531A defaults to +2.5V as required at the input of the PCM4204. So the resistor connecting the  $V_{OCM}$  input of the THS4531A to the input common-mode drive from the PCM4204 is optional and no performance change was noted with it connected or removed. The EVM power connections were modified by connecting positive supply inputs, +15V, +5VA and +5VD, to a +5V external power supply (EXT +3.3 was not used) and connecting -15V and all ground inputs to ground on the external power supply so only one external +5V supply was needed to power all devices on the EVM.

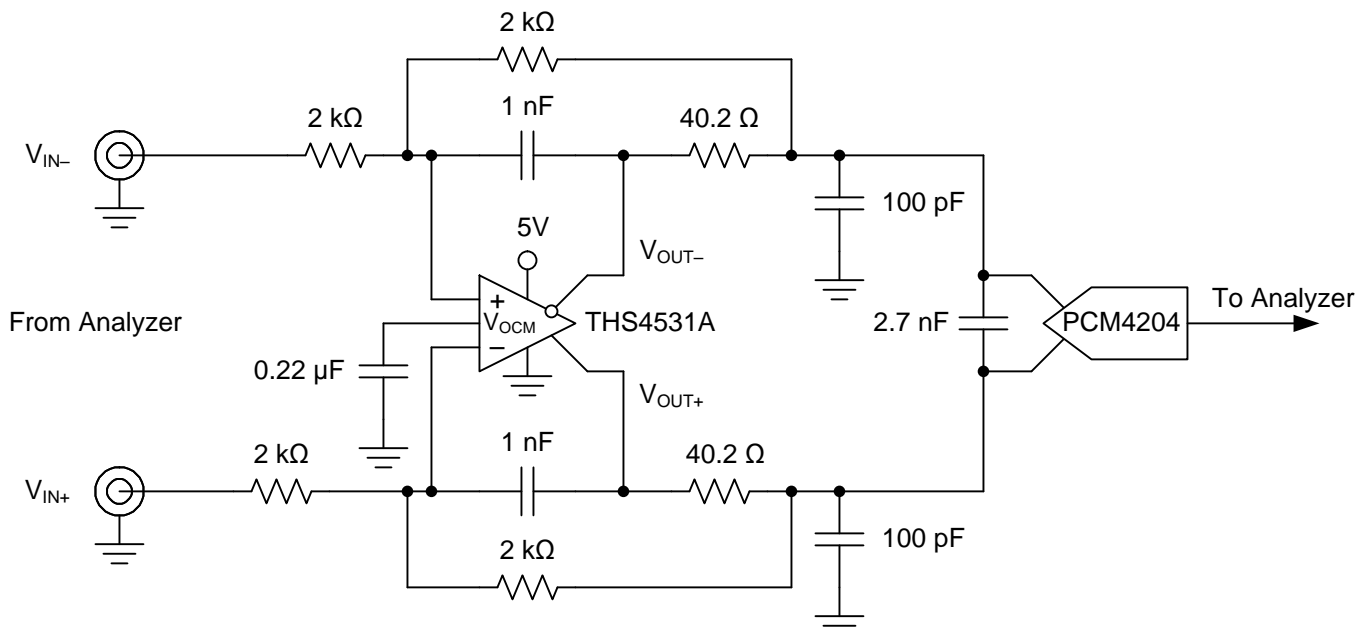

Figure 88. THS4531A and PCM4204 Test Circuit

# THS4531A

SLOS823A – DECEMBER 2012 – REVISED JANUARY 2013

www.ti.com

An audio analyzer is used to provide an analog audio input to the EVM and the PCM formatted digital output is read by the digital input on the analyzer. Data was taken at  $f_s = 96\text{kHz}$ , and audio output uses PCM format. Other data rates and formats are expected to show similar performance in line with that shown in the data sheet.

Figure 89 shows the THD+N vs Frequency with no weighting and Figure 90 shows an FFT with 1kHz input tone. Input signal to the PCM4204 for these tests is  $-0.5\text{dBFS}$ . Table 4 summarizes results of testing using the THS4531A + PCM4204 versus typical Data Sheet performance, and show it make an excellent drive amplifier for this ADC.

Figure 89. THS4531A + PCM4204 THD+N vs Frequency with No Weighting

PCM4204 Data Sheet (typ)	1kHz	-103 dB

## SAR ADC PERFORMANCE

### THS4531A and ADS8321 Combined Performance

To show achievable performance with a high performance SAR ADC, the THS4531A is tested as the drive amplifier for the ADS8321. The ADS8321 is a 16-bit, SAR ADC that offers excellent AC and DC performance, with ultra-low power and small size. The circuit shown in Figure 91 is used to test the performance. Data was taken using the ADS8321 at  $100\text{kSPS}$  with input frequency of  $10\text{kHz}$  and signal levels  $0.5\text{dB}$  below full scale. The FFT plot of the spectral performance is in Figure 92. A summary of the FFT analysis results are in Table 5 along with ADS8321 typical data sheet performance at  $f_s = 100\text{kSPS}$ . Please refer to its data sheet for more information.

The standard ADS8321 EVM and THS4531A EVM are modified to implement the schematic in Figure 91 and used to test the performance of the THS4531A as a drive amplifier. With single supply +5V supply the output common-mode of the THS4531A defaults to +2.5V as required at the input of the ADS8321 so the  $V_{OCM}$  input of the THS4531A simply bypassed to GND with 0.22 $\mu$ F capacitor. The summary of results of the FFT analysis versus typical data sheet performance shown in Table 5 show the THS4531A will make an excellent drive amplifier for this ADC.

**THS4531A and ADS7945 Combined Performance**

To show achievable performance with a high performance SAR ADC, the THS4531A is tested as the drive amplifier for the ADS7945. The ADS7945 is a 14-bit, SAR ADC that offers excellent AC and DC performance, with low power and small size. The circuit shown in Figure 93 is used to test the performance. Data was taken using the ADS7945 at 2MSPS with input frequency of 10 kHz and signal level 0.5 dB below full scale. The FFT plot of the spectral performance is in Figure 94. A summary of the FFT analysis results are in Table 6 along with ADS7945 typical data sheet performance at  $f_s = 2$ MSPS. Please refer to its data sheet for more information.

## EVM AND LAYOUT RECOMMENDATIONS

The THS4531A EVM ([SLOU356](#)) should be used as a reference when designing the circuit board. It is recommended to follow the EVM layout of the external components near to the amplifier, ground plane construction, and power routing as closely as possible. General guidelines are:

1. Signal routing should be direct and as short as possible into and out of the op amp.
2. The feedback path should be short and direct avoiding vias if possible.
3. Ground or power planes should be removed from directly under the amplifier's input and output pins.
4. A series output resistor is recommended to be placed as near to the output pin as possible. See [Figure 80](#) "Recommended Series Output Resistor vs. Capacitive Load" for recommended values given expected capacitive load of design.
5. A 2.2 $\mu$ F power supply decoupling capacitor should be placed within 2 inches of the device and can be shared with other op amps. For split supply, a capacitor is required for both supplies.
6. A 0.1 $\mu$ F power supply decoupling capacitor should be placed as near to the power supply pins as possible. Preferably within 0.1 inch. For split supply, a capacitor is required for both supplies.
7. The  $\overline{\text{PD}}$  pin uses TTL logic levels referenced to the negative supply voltage ( $V_{\text{S}}$ ). When not used it should be tied to the positive supply to enable the amplifier. When used, it must be actively driven high or low and should not be left in an indeterminate logic state. A bypass capacitor is not required, but can be used for robustness in noisy environments.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Only one of markings shown within the brackets will appear on the physical device.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.

**Стандарт  
Электрон  
Связь**

Мы молодая и активно развивающаяся компания в области поставок электронных компонентов. Мы поставляем электронные компоненты отечественного и импортного производства напрямую от производителей и с крупнейших складов мира.

Благодаря сотрудничеству с мировыми поставщиками мы осуществляем комплексные и плановые поставки широчайшего спектра электронных компонентов.

Собственная эффективная логистика и склад в обеспечивает надежную поставку продукции в точно указанные сроки по всей России.

Мы осуществляем техническую поддержку нашим клиентам и предпродажную проверку качества продукции. На все поставляемые продукты мы предоставляем гарантию .

Осуществляем поставки продукции под контролем ВП МО РФ на предприятия военно-промышленного комплекса России , а также работаем в рамках 275 ФЗ с открытием отдельных счетов в уполномоченном банке. Система менеджмента качества компании соответствует требованиям ГОСТ ISO 9001.

Минимальные сроки поставки, гибкие цены, неограниченный ассортимент и индивидуальный подход к клиентам являются основой для выстраивания долгосрочного и эффективного сотрудничества с предприятиями радиоэлектронной промышленности, предприятиями ВПК и научно-исследовательскими институтами России.

С нами вы становитесь еще успешнее!
