## Functional Description

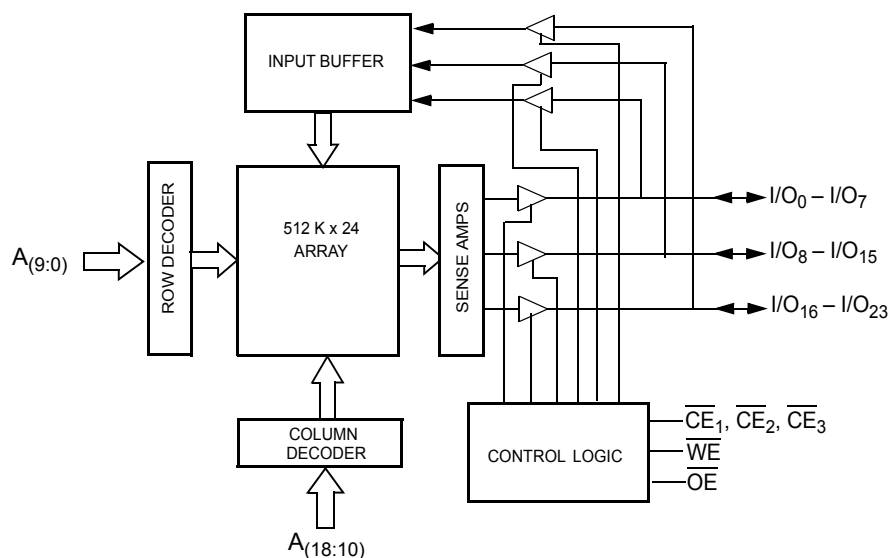

The CY7C1012DV33 is a high performance CMOS static RAM organized as 512K words by 24 bits. Each data byte is separately controlled by the individual chip selects ( $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$ ).  $\overline{CE}_1$  controls the data on the I/O<sub>0</sub>–I/O<sub>7</sub>, while  $\overline{CE}_2$  controls the data on I/O<sub>8</sub>–I/O<sub>15</sub>, and  $\overline{CE}_3$  controls the data on the data pins I/O<sub>16</sub>–I/O<sub>23</sub>. This device has an automatic power down feature that significantly reduces power consumption when deselected.

Writing the data bytes into the SRAM is accomplished when the chip select controlling that byte is LOW and the write enable input ( $\overline{WE}$ ) input is LOW. Data on the respective input and output (I/O) pins is then written into the location specified on the address pins (A<sub>0</sub>–A<sub>18</sub>). Asserting all of the chip selects LOW and write enable LOW writes all 24 bits of data into the SRAM. Output enable ( $\overline{OE}$ ) is ignored while in WRITE mode.

Data bytes are also individually read from the device. Reading a byte is accomplished when the chip select controlling that byte is LOW and write enable ( $\overline{WE}$ ) HIGH, while output enable ( $\overline{OE}$ ) remains LOW. Under these conditions, the contents of the memory location specified on the address pins appear on the specified data input and output (I/O) pins. Asserting all the chip selects LOW reads all 24 bits of data from the SRAM.

The 24 I/O pins (I/O<sub>0</sub>–I/O<sub>23</sub>) are placed in a high impedance state when all the chip selects are HIGH or when the output enable ( $\overline{OE}$ ) is HIGH during a READ mode. For more information, see the [Truth Table on page 10](#).

### Notes

- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, and input pulse levels of 0 to 3.0 V. Test conditions for the read cycle use output loading as shown in part (a) of [Figure 2 on page 5](#), unless specified otherwise.
- $t_{POWER}$  gives the minimum amount of time that the power supply is at typical  $V_{CC}$  values until the first memory access is performed.
- $\overline{CE}$  indicates a combination of all three chip enables. When active LOW,  $\overline{CE}$  indicates the  $\overline{CE}_1$  or  $\overline{CE}_2$ , or  $\overline{CE}_3$  is LOW. When HIGH,  $\overline{CE}$  indicates the  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are HIGH.
- $t_{HZOE}$ ,  $t_{HZCE}$ ,  $t_{HZWE}$ ,  $t_{LZOE}$ ,  $t_{LZCE}$ , and  $t_{LZWE}$  are specified with a load capacitance of 5 pF as in part (b) of [Figure 2 on page 5](#). Transition is measured  $\pm 200$  mV from steady state voltage.
- These parameters are guaranteed by design and are not tested.
- The internal write time of the memory is defined by the overlap of  $\overline{CE}_1$  or  $\overline{CE}_2$  or  $\overline{CE}_3$  LOW and  $\overline{WE}$  LOW. Chip enables must be active and  $\overline{WE}$  must be LOW to initiate a write. The transition of any of these signals terminate the write. The input data setup and hold timing are referenced to the leading edge of the signal that terminates the write.
- The minimum write cycle time for Write Cycle No. 3 ( $\overline{WE}$  controlled,  $\overline{OE}$  LOW) is the sum of  $t_{HZWE}$  and  $t_{SD}$ .
