## Smart Multichannel Low Side Switch with Parallel Control and SPI Interface coreFLEX

## 1 Overview

## Features

- Overvoltage, Overtemperature, ESD -Protection
- Direct Parallel PWM Control of all Channels
- safeCOMMUNICATION (SPI and Parallel)
- Efficient Communication Mode: compactCONTROL
- Compatible with 3.3 V - and 5V- Micro Controllers I/O ports
- clampSAFE for highly efficient parallel use of the channels
- Green Product (RoHS compliant)
- AEC Qualified

## Application

- Power Switch Automotive and Industrial Systems switching Solenoids, Relays and Resistive Loads

## Description

10 - channel Low-Side Switch in Smart Power Technology [SPT] with Serial Peripheral Interface [SPI] and 10 open drain DMOS output stages. The TLE8110EE is protected by embedded protection functions and designed for automotive and industrial applications. The output stages are controlled via Parallel Input Pins for PWM use or SPI Interface . The TLE8110EE is particularly suitable for Engine Management and Powertrain Systems.

### 2.1 Description

## Communication

The TLE8110EE is a 10-channel low-side switch in PG-DSO-36-41 package providing embedded protective functions. The 16 bit serial peripheral interface (SPI) can be utilized for control and diagnosis of the device and the loads. The SPI interface provides daisy-chain capability in order to assemble multiple devices in one SPI chain by using the same number of micro-controller pins.
The analogue and the digital part of the device is supplied by 5 V . Logic Input and Output Signals are then compatible to 5 V logic level [TTL - level]. Optionally, the logic part can be supplied with lower voltages to achieve signal compatibility with e.g. 3.3V logic level [CMOS - level].
The TLE8110EE is equipped with 10 parallel input pins that are routed to each output channel. This allows control of the channels for loads driven by Pulse Width Modulation (PWM). The output channels can also be controlled by SPI.

## Reset

The device is equipped with one Reset Pin and one Enable. Reset [RST] serves the whole device, Enable [EN] serves only the Output Control Unit and the Power Stages.

## Diagnosis

The device provides diagnosis of the load, including open load, short to GND as well as short circuit to $\mathrm{V}_{\text {Batt }}$ detection and over-load / over-temperature indication. The SPI diagnosis flags indicates if latched fault conditions may have occurred.

## Protection

Each output stage is protected against short circuit. In case of over load, the affected channel is switched off. The switching off reaction time is dependent on two switching thresholds. Restart of the channel is done by clearing the Diagnosis Register. This feature protects the device against uncontrolled repetitive short circuits. The reaction to a short-circuit and over-temperature can alternatively changed to further modes, such as semi- or auto - restart of the affected channel.
There is a temperature sensor available for each channel to protect the device in case of over temperature. In case of over temperature the affected channel is switched off and the Over-Temperature Flag is set. Restart of the channel is done by deleting the Flag. This feature protects the device against uncontrolled temperature toggling.

## Parallel Connection of Channels

The device is featured with a central clamping structure, so-called CLAMPsafe. This feature ensures a balanced clamping between the channels and allows in case of parallel connection of channels a high efficient usage of the channel capabilities. This parallel mode is additionally featured by best possible parameter- and thermal matching of the channels and by controlling the channels accordingly.

ESD Robustness

| 4.1 .22 | Electro Static Discharge Voltage <br> "Human Body Model - HBM" | $V_{\text {ESD }}$ | -4 | 4 | kV | All Pins <br> $\mathrm{HBM}^{3)}$ <br> $1.5 \mathrm{KOhm}, 100 \mathrm{pF}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 4.1 .23 | Electro Static Discharge Voltage <br> "Charged Device Model - CDM" | $V_{\text {ESD }}$ | -500 | 500 | V | All Pins <br> CDM $^{4}$ |
| 4.1 .24 | Electro Static Discharge Voltage <br> "Charged Device Model - CDM" | $V_{\text {ESD }}$ | -750 | 750 | V | Pin 1, 18, 19, 36 <br> $($ (corner pins $)$ <br> CDM $^{4)}$ |

1) Only one single channel at one time.
2) triangular test pulse
3) ESD susceptibility, HBM according to EIA/JESD 22-A114-B
4) ESD susceptibility, Charged Device Model "CDM" EIA/JESD22-C101-C

Note: Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note: Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as "outside" normal operating range. Protection functions are not designed for continuous repetitive operation.

### 4.2 Functional Range

| Pos. | Parameter | Symbol | Limit Values |  | Unit | Conditions |

## $5 \quad$ Power Supply

### 5.1 Description Power Supply

The TLE8110EE is supplied by analogue power supply line $V_{D D}$ which is used for the analogue functions of the device, such as the gate control of the power stages. The digital power supply line $\mathrm{V}_{\mathrm{CC}}$ is used to supply the digital part and offers the possibility to adapt the logic level of the serial output pins to lower logic levels.

Figure 6 Block Diagram Supply and Reset

## Description Supply

The Supply Voltage Pins are monitored during the power-on phase and under normal operating conditions for under voltage.
If during Power-on the increasing supply voltage exceeds the Supply Power-on Switching Threshold, the internal Reset is released after an internal delay has expired.
In case of under voltage, a device internal reset is performed. The Switching Threshold for this case is the Poweron Switching threshold minus the Switching Hysteresis.
In case of under voltage on the analogue supply line $V_{D D}$ the outputs are turned off but the content of the registers and the functionality of the logic part is kept alive. In case of under voltage on the digital supply $\mathrm{V}_{\mathrm{CC}}$ line, a complete reset including the registers is performed.

After returning back to normal supply voltage and an internal delay, the related functional blocks are turned on again. For more details, refer to the chapter "Reset"
The device internal under-voltage set will set the TOR bit and the related bits in SDS (Short Diagnosis and Device Status) to allow the micro controller to detect this reset. For more information, refer to the chapter "Control of the Device".

## 6 Reset and Enable Inputs

### 6.1 Description Reset and Enable Inputs

The TLE8110EE contains one Reset- and one Enable Input Pin as can be seen in Figure 6.

Description:
Reset Pin $[\overline{R S T}]$ is the main reset and acts as the internal under voltage reset monitoring of the digital supply voltage $\mathrm{V}_{\mathrm{Cc}}$ : As soon as $\overline{\mathrm{RST}}$ is pulled low, the whole device including the control registers is reset.

The Enable Pin [EN] resets only the Output channels and the control circuits. The content of the all registers is kept. This functions offers the possibility of a "soft" reset turning off only the Output lines but keeping alive the SPI communication and the contents of the control registers. This allows the read out of the diagnosis and setting up the device during or directly after Reset.

### 6.2 Electrical Characteristics Reset Inputs

FLEX Smart Multi-Channel Switch

## Power Outputs

## $7 \quad$ Power Outputs

### 7.1 Description Power Outputs

The TLE8110EE is a 10 channel low-side powertrain switch. The power stages are built by N -channel power MOSFET transistors. The device is a universal multichannel switch but mostly suited for the use in Engine Management Systems [EMS]. Within an EMS, the best fit of the channels to the typical loads is:

- Channel 1 to 4 for Injector valves or mid-sized solenoids with a nominal current requirement of 1.5A.
- Channel 5 to 6 for mid-sized solenoids or Injector valves with a nominal current requirement of 1.7 A
- Channel 7 to 10 for small solenoids or relays with a nominal current requirement of 0.75 A

Channel 1 to 10 provide enhanced clamping capabilities of typically 55 V best suited for inductive loads such as injector valves. It is recommended in case of an inductive load, to connect an external free wheeling- or clamping diode, where-ever possible to reduce power dissipation.
All channels can be connected in parallel. Channels 1 to 4,5 to 6 and 7 to 10 are prepared by matching for parallel connection with the possibility to use a high portion of the capability of each single channel also in parallel mode (refer to Chapter 7.4).
Channel 5 and 6 have a higher current shut down threshold to allow to connect in parallel mode a load with a high inrush-current, such as a lambda sensor heater.

Figure 9 Block Diagram of Control and Power Outputs

FLEX

### 7.2 Description of the Clamping Structure

When switching off inductive loads, the potential at pin OUT rises to $\mathrm{V}_{\mathrm{DS}(\mathrm{CL})}$ potential, because the inductance intends to continue driving the current. The voltage clamping is necessary to prevent destruction of the device, see Figure 10 for the principle clamping circuit. Nevertheless, the maximum allowed load inductance is limited.

Figure 10 Principle Clamping Structure

## Maximum Load Inductance

During demagnetization of inductive loads, energy has to be dissipated in the device. This energy can be calculated with following equation:
$E=V_{\mathrm{DS}(\mathrm{CL})} \cdot\left[\frac{V_{\mathrm{batt}}-V_{\mathrm{DScl}}}{R_{\mathrm{L}}} \cdot \ln \left(1-\frac{R_{\mathrm{L}} \cdot I_{\mathrm{L}}}{V_{\mathrm{batt}}-V_{\mathrm{DScl}}}\right)+I_{\mathrm{L}}\right] \cdot \frac{L}{R_{\mathrm{L}}}$
Following equation simplifies under the assumption of $R_{\mathrm{L}}=0$ :
$E=\frac{1}{2} L I_{\mathrm{L}}{ }^{2} \cdot \frac{V_{\mathrm{DScl}}}{V_{\mathrm{DScl}}-V_{\mathrm{Batt}}}$
The maximum energy, which is converted into heat, is limited by the thermal design of the component.

The Repetitive Clamping Energies $E_{\mathrm{AR}}$ as defined in the following Chapter 7.3, Item 7.3.4 (and following items) are representing cummulated operating scenarios for one channel group with:

- normal operating condition with a typical battery voltage of $\mathrm{V}_{\text {Batt }}=16 \mathrm{~V}$ and an ambient temperature of typically $\mathrm{T}_{\mathrm{a}}=125^{\circ} \mathrm{C}$.
- cold operation with a typical battery voltage of typically $\mathrm{V}_{\text {Batt }}=13.5 \mathrm{~V}$ and an ambient temperature of typically $\mathrm{T}_{\mathrm{a}}=-40^{\circ} \mathrm{C}$.
- generator defect with a typical battery voltage of $\mathrm{V}_{\text {Batt }}=18 \mathrm{~V}$ and an ambient temperature of typically $\mathrm{T}_{\mathrm{a}}=135^{\circ} \mathrm{C}$. The Power Dissipation $P_{v}$ is typically considered with $P_{v}=3 W$ during normal operation. This power dissipation changes during the other operating conditions according the thermal behaviour of $R_{\mathrm{DSon}}$ and the load Resistance $R_{\mathrm{L} .}$ The interaction of both, together with an assumed typical $\mathrm{R}_{\mathrm{thja}}=7.5 \mathrm{~K} / \mathrm{W}$, the given average junction temperature $\mathrm{T}_{\mathrm{j}}$ is considered as the start temperature for the clamping process.
Due to the fact, that the maximum possible Repetitive Clamping Energy $E_{\text {AR }}$ varies with the Load Current $I_{\mathrm{D}}$, partially optional operating points are specified within the scenarios. Those optional operating points are not considered as cummulative clamping pulses to the scenario.

### 7.4 Parallel Connection of the Power Stages

The TLE8110EE is equipped with a structure which improves the capability of parallel-connected channels. The device can be "informed" via the PMx.PMx - bits (see chapter control of the device) which of the channels are connected in parallel. The input channels can be mapped to the parallel connected output channels in order to apply the PWM signals. This feature allows a flexible adaptation to different load situations within the same hardware setup.
In case of overload the ground current and the power dissipation is increasing. The application has to take into account that all maximum ratings are observed (e.g. operating temperature $T_{J}$ and total ground current $I_{\mathrm{GND}}$, see Maximum Ratings). In case of parallel connection of channels with or w/o PM-bit set, the maximum clamping energy defined by the derating factor must not be exceeded.

All stages are switched on and off simultaneously. The $\mu \mathrm{C}$ has to ensure that the stages which are connected in parallel have always the same state (on or off). The PM-bit should be set according to the parallel connected power stages in order to achieve the best possible de-rating factors.

FLEX

The performance during parallel connection of channels is specified by design and not subject to the production test. The given factors are maximum values.

All channels at the same junction temperature level.

## I_FACTOR

The maximum operating current $\mathrm{I}_{\mathrm{DSD}, \mathrm{OUTxy}(\mathrm{sum})}$ is the minimum "Current Shut-down Threshold Low" $\mathrm{I}_{\mathrm{DSD} \text { (low),n(min) }}$.

- $I_{D S D, O U T x y(s u m)}=I_{-F A C T O R}{ }^{\operatorname{SUM}\left[I_{D S D(I o w), n(m i n)}\right]}$ with I_FACTOR $=1$.

The typical maximum operating current $I_{D S D, O U T x y(s u m)}$ is the "Current Shut-down Threshold Typ" $I_{D S D(t y p), n(m i n)}$.

- $I_{D, O U T x y(s u m)}=I \_F A C T O R * \operatorname{SUM}\left[I_{D(t y p), n}\right]$

## E_FACTOR

The Maximum Clamping Energy $\mathrm{E}_{\text {ARxy(sum) }}$ of parallel connected channels is defined as follows:

- $\mathrm{E}_{\mathrm{AR}, \mathrm{xy}(\text { sum })}=\mathrm{E}_{-} \mathrm{FACTOR}$ * $\operatorname{SUM}\left[\mathrm{E}_{\mathrm{AR}, n}\right]$ at $\mathrm{Tj}=150^{\circ} \mathrm{C}$ and $\mathrm{I}_{\mathrm{D}}=\mathrm{I}_{\mathrm{Dnom}}$

## ON-Resistance

The typical ON-Resistance $R_{\text {DSon,xy(sum) }}$ of parallel connected channels is sum of the typical RDSon $R_{\text {DSon,n(typ) }}$ defined as follows

- $R_{\mathrm{DSon}, \mathrm{xy}(\mathrm{sum})}=1 /\left[1 / R_{\mathrm{DSon}, n(t \mathrm{typ})}+1 / R_{\mathrm{DSon}, n+1(\text { typ })}\right]$

## 8 Diagnosis

### 8.1 Description Diagnosis

The TLE8110EE provides diagnosis information about the device and about the load. Following diagnosis flags have been implemented for each channel:

- The diagnosis information of the protective functions, such as "over current" and"over temperature"
- The open load diagnosis
- The short to ground information.

Updating the Diagnosis is based on a filter-dependent standard delay time of typ. $150 \mu \mathrm{~s}$. This value is set as a default.
Refer to Figure 16 for details.

## Application Hint:

In specific application cases - such as driving Uni-Polar Stepper Motor - it might be possible, that reverse currents flow for a short time, which possibly can disturb the diagnosis circuit at neighboring channels and cause wrong diagnosis results of those channels. To reduce the possibility, that this effect appears in a certain timing range, the filter time of Channels 7 to 10 can be extended to typ. 2.5 ms or typ. 5 ms by setting the "Diagnosis Blind Time" - Bits (DBTx). If Channels 7 to 10 are used for driving loads causing reverse currents, they influence each other and additionally might affect Channels 5 and 6 . It is recommended to use the channels $7+8$ and $9+10$ as pairs for anti-parallel control signals, such as for the stepper motors. For logic setting details, see chapter "Control of the Device"

## $9 \quad$ Parallel Inputs

### 9.1 Description Parallel Inputs

There are 10 input pins available are on TLE8110EE to control the output stages.
Each input signal controls the output stages of its assigned channel. For example, IN1 controls OUT1, IN2 controls OUT2, etc.

A "Low"-Signal at INx switches the related Output Channel off. The zener diode protects the input circuit against ESD pulses.
For details about the Boolean operation, refer to the chapter "Control of the device", for details about timing refer to Figure 11.

Protection Functions

## 10 Protection Functions

The device provides embedded protective functions. Integrated protection functions are designed to prevent IC destruction under fault conditions described in this Document. Fault conditions are considered "outside" the normal operating range. Protection functions are not designed for continuous repetitive operation.
There is an over load and over temperature protection implemented in the TLE8110EE.
If a protection function becomes active during the write cycle of Diagnosis Information into the Diagnosis Register, the information is latched and stored into the diagnosis register after the write process.

In order to achieve a maximum protection, the affected channel with over current or over temperature is switched off. The device can be configured via serial communication interface in three ways in order to react on this fault condition:

- after switching off, turning on again after a delay time: In case of over temperature, when the temperature has decreased below the temperature shut down threshold. In case of over-current, the affected channel is turning on after a delay time until the over temperature protection is activated.
- after switching off, turning on again the affected channel with the next parallel or serial control command.
- Default Setting: after switching off latching the condition and remain off until the Diagnosis Register is cleared via serial control. In this case, the internal Diagnosis Bits for Over Temperature and Over Current are cleared with the rising edge of $\overline{\text { S_CS }}$
For the failure condition of Reverse Currents, the device contains a "Reverse Current Protection Comparator" [RCP]. This RCP can optionally be activated by setting the DEVS.RCP Bit.
In case the comparator is activated, it detects a reverse current and switches $O N$ the related output channel. The channel is kept ON up to a reverse current channel dependent threshold $I_{\text {RCP_off. }}$. This threshold is defined by regulators target value to keep the output voltage at $>/ \sim-0.3 \mathrm{~V}$. If the current exceeds a defined value, the comparator switches OFF and other protection functions are protecting the circuit against reverse current. That means that at higher currents / or in case RCP is de-activated / not activated, the reverse current is flowing through the body diode of the DMOS. In that case, the voltage drops to typically -0.6 V according the voltage of the body diode. In case the comparator threshold has been exceeded and the RCP has been switched OFF, the functions remains OFF until the reverse current arrives back to zero reverse current. Only then, the comparator can be activated again after a delay time $t_{\text {RCP_on_delay }}$.
This function reduces the un-wanted influence of a reverse current to the analogue part of the circuit (such as the diagnosis). For more details about the functionality, see Figure 21 and Figure 22 and concerning the settings and the related registers, refer to Chapter "Control of the Device".

Figure 19 gives an overview about the protective functions.

## 11 16 bit SPI Interface

### 11.1 Description 16 bit SPI Interface

The diagnosis and control interface is based on a serial peripheral interface (SPI).
The SPI is a full duplex synchronous serial slave interface, which uses four lines: S_SO, S_SI, S_CLK and $\overline{\text { S_CS }}$. Data is transferred by the lines S_SI and S_SO at the data rate given by S_CLK. The falling edge of $\overline{S_{-} C S}$ indicates the beginning of a data access. Data is sampled in on line S_SI at the falling edge of S_CLK and shifted out on line SO at the rising edge of SCLK. Each access must be terminated by a rising edge of $\bar{S} \_C S$. A modulo 8 counter ensures that data is taken only, when a multiple of 8 bit has been transferred. If in one transfer cycle not a multiple of 8 bits have been counted, the data frame is ignored. The interface provides daisy chain capability.

Figure 2316 bit SPI Interface
The SPI protocol is described in Chapter "Control of the device". Concerning Reset of the SPI, please refer to the chapter "Reset"

## 12 Control of the device

This chapter describes the SPI-Interface signals, the protocol, registers and commands. Reading this chapter allows the Software Engineer to control the device. The chapter contains also some information about communication safety features of the protocol.

### 12.1 Internal Clock

The device contains an internal clock oscillator.

## Electrical Characteristics: Diagnostics

$3 \mathrm{~V}<V_{\mathrm{CC}}<5.5 \mathrm{~V} ; 4.5 \mathrm{~V}<V_{\mathrm{DD}}<5.5 \mathrm{~V} ; V_{\text {batt }}=13.5 \mathrm{~V}, T_{\mathrm{j}}=-40^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$, all voltages with respect to ground, positive current flowing into pin

### 12.2 SPI Interface. Signals and Protocol

### 12.2.1 Description 16 bit SPI Interface Signals

## $\overline{\text { S_CS }}$ - Chip Select:

The system micro controller selects the TLE8110EE by means of the $\overline{S \_C S}$ pin. Whenever the pin is in low state, data transfer can take place. When $\overline{S \_C S}$ is in high state, any signals at the S_CLK and S_SI pins are ignored and S_SO is forced into a high impedance state.

## S_CS High to Low transition: $\sim$

- The information to be transferred loaded into the shift register (16-bit Protocol).
- S_SO changes from high impedance state to high or low state depending on the logic OR combination between the transmission or error flag [TOR] (see Chapter 12.2.4.3) and the signal level at pin S_SI. As a result, even in daisy chain configuration, a high signal indicates a faulty transmission or an existing error on one of the Output Channels. The transmission error flag is set after RST, so a reset between two SPI commands is indicated.

## S_CS Low to High transition:

- Command decoding is only done, when after the falling edge of CS exactly a multiple ( $1,2,3, \ldots$ ) of eight S_CLK signals have been detected. (See Modulo-8 Counter: Chapter 12.2.4.2)

## S_CLK - Serial Clock:

This input pin clocks the internal shift register. The serial input (S_SI) transfers data is shifted into the register on the falling edge of S_CLK while the serial output (S_SO) shifts the information out on the rising edge of the serial clock. It is essential that the S_CLK pin is in low state whenever chip select CS makes any transition.

## S_SI - Serial Input:

Serial input data bits are shifted in at this pin, the most significant bit first. The bit at the S_SI Pin is read on the falling edge of S_CLK.

## S_SO Serial Output:

Data is shifted out serially at this pin, the most significant bit first. S_SO is in high impedance state until the $\overline{\text { S_CS }}$ pin goes to low state.The next bits will appear at the S_SO pin following the rising edge of S_CLK.

### 12.2.2 Daisy Chain Capability

The SPI-Interface of TLE8110EE provides daisy chain capability. In this configuration several devices are activated by the same $\overline{S \_C S}$ signal. The S_SI line of one device is connected with the S_SO line of another device (see Figure 25), which builds a chain. The ends of the chain are connected with the output and input of the master device, S_SO and S_SI respectively. The master device provides the master clock CLK, which is connected to the S_CLK line of each device in the chain. By each clock edge on S_CLK, one bit is shifted into the S_SI. The bit shifted out can be seen at SO. After 16 S_CLK cycles, the data transfer for one device has been finished. In single chip configuration, the $\overline{S \_C S}$ line must go high to make the device accept the transferred data. In daisy chain configuration the data shifted out at device 1 has been shifted in to device 2. Example: When using three devices in daisy chain, three times 16 bits have to be shifted through the devices. After that, the $\overline{\mathrm{S}} \mathrm{CS}$ line must go high (see Figure 25).

SPI_DasyChain2.emf
Figure 25 Principle example for Data Transfer in Daisy Chain Configuration
Note: Due to the integrated modulo 8 counter, 8 bit and 16 bit devices can be used in one daisy chain.

### 12.2.3 SPI Protocol

The device contains two protocol styles which are applied dependent of the used commands. There is the standard 16 -bit protocol and the $2 \times 8$-bit protocol. Both protocols can appear also be mixed.

### 12.2.3.1 16-bit protocol

Each Cycle where a serial data or command frame is sent to the S_SI of the SPI interface, a data frame is returned at the same time by the S_SO The content of the S_SO frame is dependent on the previous command which has been sent to S_SI. Read Command ( $R / W=R$ ) returns one cycle later the content of the addresses register. (see Figure 26 ).

| ADDR | $14: 12$ | Address <br> Address which has bin addressed |
| DATA | $11: 0$ | Data <br> Content of Address or feedback Data |

Note: Reading a register needs two SPI frames. In the first frame the RD command is sent. In the second frame the output at SPI signal SO will contain the requested information. A new command can be executed in the second frame.

### 12.2.3.2 2x8-bit protocol

Each Cycle where a serial data or command frame is sent to the S_SI of the SPI interface, a data frame is returned at the same time by the S_SO. The content of the S_SO frame is dependent of the previous command which has been sent to S_SI and the content of the actual content of S_SI: The first Upper Byte send to S_SI controls the content of the Lower Byte actual returned by S_SO. The Lower Byte send to S_SI controls the Lower Byte in S_SO of the next frame. (see Figure 27 ).

| TOR | CS | Transmission or Output Error (see Chapter 12.2.4.2) <br> 0 <br> 1 <br> Previous transmission was successful, no error, no reset. <br> Previous transmission failed, Error on one of the Output Channels, under voltage <br> reset* or first transmission after reset. <br> * OR operated diagnosis information of all Output Channels. (To read out details <br> perform CMD_SDS, see Chapter 12.3.1) |
| Upper Byte | $15: 8$ | Upper Byte <br> contains the data according the command and data in the Lower Byte of the previous <br> communication Frame. |
| Lower Byte | $7: 0$ | Lower Byte <br> contains the data according the command in the Upper Byte of the actual communication <br> frame |

Note: Reading a register needs two SPI frames. In the first frame the RD command is sent. In the second frame the output at SPI signal SO will contain the requested information. A new command can be executed in the second frame.

### 12.2.3.3 16-and $2 \times 8$-bit protocol mixed.

The 16 -bit and $2 \times 8$-bit protocols are mixed according the used commands (see Chapter 12.3.1). Specially care should be taken, changing from the 16 -bit protocol to the $2 \times 8$-bit protocol. In this case, it is important to send a NOP command to S_SI. Otherwise, by sending instead a Command, a collision between the S_SO data in the following frame and the Lower Byte of the $2 \times 8$-bit protocol will happen (see Chapter 12.2.3.2).

FLEX

Control of the device

Figure 28 16-bit protocol

### 12.2.4 safeCOMMUNICATION

The devise contains some safety features, which are improving the protecting of the application against malfunction in case of disturbance of the communication between the Micro Controller and the Device:

### 12.2.4.1 Encoding of the commands

The Commands are encoded. In case other bit-patterns, then the defined once are received, the commands are ignored and the communication error is indicated in the TOR-Bit (see Chapter 12.2.4.3) and can be read out in detail with the command CMD_RSDS (seeChapter 12.3.1.2).

### 12.2.4.2 Modulo-8 Counter

The modulo is the integral remainder in integral division. In data communications, a modulo based approach is used to ensure that user information in SPI protocols is in the correct order. The device has a receiver-side counter, and a defined counter size. The modulo counter specifies the number of subsequent numbers available. In case of TLE8110EE Modulo 8 counter specifies 8 serial numbers. The modulo 8 counter ensures that data is taken only, when a multiple of 8 bit has been transferred. If in one transfer cycle not a multiple of 8 bits have been counted, the data frame is ignored and a Communication Error is indicated in the TOR-Bit (see Chapter 12.2.4.3) and in the CMD_RSDS - Feedback (seeChapter 12.3.1.2).

## Control of the device

### 12.2.4.3 TOR - Transmission or Diagnosis Error Bit

As described in Chapter 12.2.3.1 and Chapter 12.2.3.2 the Transmission or Diagnosis Error bit [TOR] appears on S_SO, as soon as CS makes a High-to-LOW transition until the first rising edge of the clock signal. The TOR contains ONLY error information which has appeared in and since last frame. TOR does not contain any latched information.

- Command Ignored and Modulo 8: In the next frame after the error, the TOR bit will be set once.
- Under voltage: After digital- or analogue under voltage, the TOR of the first transmission contains the error information. In the following transmissions, the information is not shown anymore. But the under voltage information is latched in the CMD_CSDS bit until it is cleared (see Chapter 12.3.1).
- OR operated Diagnosis or protection error information: If one of those errors has appeared since the last frame, the information change is shown in the TOR bit. (The error is latched in the related Diagnosis and Error register and remains there until it is cleared). But the TOR bit will show the information-change only once. In the next frame, the TOR bit is cleared again

The information about the data transmission, TOR contains, is always from the previous transmission. The Diagnosis information, the Bit contains is the status of the diagnosis until the CS high-to-low transition. Changes in the diagnosis during the transmission are latched and stored until the next read-out cycle. By read-out of the TOR-bit, no stored information is cleared. The Error information can be read out in detail, by sending the command CMD_SDS and can be cleared (NOT Diagnosis Error) by the command CMD_CSDS (see Chapter 12.3.1)
In order to reduce the Micro Controller work load, it is possible to read out the TOR bit also without constructively data transfer. That means, by just toggling CS, the status can be read out.
To allow using the TOR Bit also in SPI-Daisy-Chain configuration, the TOR-Bit is OR operated with S_SI which contains the TOR information of the previous device in the Daisy-Chain.

### 12.3 Register and Command - Overview

This Chapter describes the Registers and Commands. The commands allow to carry through some actions, such as reading out or clearing the diagnosis or reading out the Input Pins.

Specially highlighted here should be the encoded CMD_DMSx/OPSx commands - compactCONTROL - , a highly efficient command-set to set a part of the output pins and read out the diagnosis at the same time. Included in this command set is the possibility to check, if the communication works well as also the possibility to read-out some of the parallel Input Pins INx. Using this compact command set can reduce the workload of the micro-controller during run-time significantly.
CMD_RSD is preformed and short diagnostics [SD] is returned after each Write Cycle to any of the writable registers.
After start-up of the device, the registers are loaded with the default settings as described below in the register descriptions. The Registers are cleared and set back to the default values, when a low signal is applied to the pin $\overline{\text { RST }}$ or an under-voltage condition appears at the supply pin $V_{c c}$ what causes an under-voltage reset. If a low signal at pin EN is applied or an under-voltage condition appears at pin $\mathrm{V}_{\mathrm{DD}}$, the Registers are not cleared.

### 12.3.1.4 CMD_RINx - Command: Return Input Pin (INx) -Status

The Command CMD_RINx offers the possibility to read out the actual status of the Input Pins. This command allows to check the correct communication on the INx Pins. The data to be send is latched at the end of the command frame .

### 12.3.2 DCC - Diagnosis Registers and compactCONTROL

The DCC - Diagnosis and Compact Control Set allows to read out and clear the Diagnosis Registers. Additionally this Command set offers the possibility to proceed with a compactCONTROL Mode using DMS - Diagnosis Mode Set and OPS - Output Pin Set Commands. This compactCONTROL Mode offers the possibility to Control the device with lowest work load on the micro controller side.
If any other pattern then the defined commands is received on S_SI, the command is ignored and rated as a Communication Error. In this case, this incident is reported in SDS (Chapter 12.3.1.2) and TOR (Chapter 12.2.4.3).

If an Error in the Output Channels is detected by the diagnosis circuit, the result is latched in the diagnosis registers related to each channel.
The Diagnosis Register is not deleted, when it is just read out. The Diagnosis Register byte can only be cleared by using the appropriated command. In this case, the complete Register Bank is cleared. The separation in two diagnosis register banks allows together with the Device Control Bits "Latch on Over Current or Over Temperature" [LOTC] a separated handling of the channel groups. The groups of Channel 1 to 6 and 7 to 10 can be treated separately in this case. For details, see also chapter Chapter 12.3.6.

### 12.3.2.3 DMSx/OPSx - Diagnosis Mode Set / Output Pin Set Commands

## Protocol

Each Cycle where a serial data or command frame is sent to the Serial Input [SI] of the SPI interface, a data frame is returned immediately by the Serial Output [SO]. The content of the SO frame is dependent of the previous command which has been sent to SI and the content of the actual content of SI: The first Byte send by S_SI controls the content of the second byte actual returned by S_SO. The second Byte send by S_SI controls the first byte in S_SO of the next frame. (see Figure 37)

FLEX

Control of the device

### 12.3.3 OUTx - Output Control Register CHx

The Output Control Register OUTx consists of 10 Bits to control the Output Channel. Each Bit switches ON/OFF the related Channel.

OUTx becomes only active when ISx[1:0] = 0x. For details refer to Chapter 12.3.4.

| OUTx <br> Output Control Register |
| :--- |
|  |
| 11 |

| Field | Bits | Type | Description |
| :--- | :--- | :--- | :--- |
| OUTx[9:0] | $9: 0$ | R/W | Data - OUTx[9:0] <br> OUTx = 0 According Channel is switched OFF <br> OUTx = 1 According Channel is switched ON <br> default (all channels OFF) OUT[9:0] $=0000000000_{\mathrm{B}}=000_{\mathrm{h}}$ |
| OUT[11:10] | $11: 10$ | R/W | Data - OUTx[11:10] <br> bits are set to OUT[11:10] $=1$. |

### 12.3.4 ISx - INPUT or Serial Mode Control Register, Bank A and Bank B

The INPUT or Serial Control Register [ ISx[1:0] ] allows to define the way of controlling the Output Channels. There are 4 setting options possible:

- Standard Serial Control: The related Output Channel is set according the content of the OUTx Register. (Chapter 12.3.3)
- A further possibility is the control by the Input Pins
- The settings of the Parallel Mode Register PMx[0]. (Chapter 12.3.5)
- Additionally possible is the AND operation between the setting of the OUTx register and the PWM signal at the INPUT Pin.

COMMAND

### 12.3.5 PMx - Parallel Mode Register CHx

The Parallel Mode Register PMx[1] allows to "inform" the device about externally parallel connected output channels. If a PMx bit is set, the "lower" related Input Channel controls the indicated Output Channels to achieve best possible matching and according to that highest efficiency of both channels. Additionally to that, the CLAMPsafe feature allows high matching during clamping.

| PMx |  |  |  |  |  |  |  |  |  |  | MAND |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Field | Bits | Type | Description |
| :--- | :--- | :--- | :--- |
| PMx | $11: 8$ | R/W | 0 |
| PMx | $7: 0$ | R/W | PMx - Parallel Mode Bit  <br> 0 Direct Mode <br> $1 \quad$ Parallel Mode of Channel 1 with x+1  <br> default PMx[0] = 0  <br> Controlling Parallel Mode is possible between Channel 1 to 4,5 to 6,  <br> 7 to 10. In between the groups, no parallel mode is supported  <br> but possible.  |
|  |  | In case Parallel Mode is chosen and a diagnosis error at only one of <br> the channels is detected, the according diagnosis bit is set. This <br> information mismatch can be caused by tolerance related in- <br> balance of the channels connected together in parallel mode. <br> The diagnosis bits should be or-operated by the Micro Controller <br> side. |  |

### 12.3.6 DEVS - Device Settings

This Register allows additional Device settings. For details refer also to the Chapter "Electrical Characteristics". The Diagnosis Current Control register allow to select between different Diagnosis Modes. The Diagnosis Currents can be switched off to avoid glowing of any connected LEDs.

FLEX

Control of the device

The Register Latch on Over Current or Over Temperature LOTC[1:0] defines the reaction of the protection functions on exceeding the operating ranges.

## 13 Package Outlines

1) Does not include plastic or metal protrusion of 0.15 max. per side
2) Does not include dambar protrusion of 0.05 max. per side
3) Distance from leads bottom (= seating plane) to exposed diepad

Figure 38 PG-DSO-36-41 Exposed Pad

## Green Product (RoHS compliant)

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).

You can find all of our packages, sorts of packing and others in our Infineon Internet Page "Products": http://www.infineon.com/products.

With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

## Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

## Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.
Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

## Стандарт Злектрон Связь

Мы молодая и активно развивающаяся компания в области поставок электронных компонентов. Мы поставляем электронные компоненты отечественного и импортного производства напрямую от производителей и с крупнейших складов мира.

Благодаря сотрудничеству с мировыми поставщиками мы осуществляем комплексные и плановые поставки широчайшего спектра электронных компонентов.

Собственная эффективная логистика и склад в обеспечивает надежную поставку продукции в точно указанные сроки по всей России.

Мы осуществляем техническую поддержку нашим клиентам и предпродажную проверку качества продукции. На все поставляемые продукты мы предоставляем гарантию.

Осуществляем поставки продукции под контролем ВП МО РФ на предприятия военно-промышленного комплекса России, а также работаем в рамках 275 ФЗ с открытием отдельных счетов в уполномоченном банке. Система менеджмента качества компании соответствует требованиям ГОСТ ISO 9001.

Минимальные сроки поставки, гибкие цены, неограниченный ассортимент и индивидуальный подход к клиентам являются основой для выстраивания долгосрочного и эффективного сотрудничества с предприятиями радиоэлектронной промышленности, предприятиями ВПК и научноисследовательскими институтами России.

С нами вы становитесь еще успешнее!
