

FEATURES

Low noise

Voltage noise: 3 nV/ $\sqrt{\text{Hz}}$

Current noise: 3 pA/ $\sqrt{\text{Hz}}$

Small-signal BW: 115 MHz

Large-signal BW: 2 V p-p = 80 MHz

Slew rate: 550 V/ μs , 2 V p-p

Gain ranges (specified)

-14 dB to +46 dB

0 dB to 60 dB

Gain scaling: 50 dB/V

DC-coupled

Single-ended input and output

Supplies: $\pm 3\text{ V}$ to $\pm 12\text{ V}$

Temperature range: -55°C to $+125^{\circ}\text{C}$

Power

150 mW @ $\pm 3\text{ V}$, $-55^{\circ}\text{C} < T < +125^{\circ}\text{C}$

84 mW @ $\pm 3\text{ V}$, PWRA = 3 V

APPLICATIONS

Industrial process controls

High performance AGC systems

I/Q signal processing

Video

Industrial and medical ultrasound

Radar receivers

GENERAL DESCRIPTION

The AD8336 is a low noise, single-ended, linear-in-dB, general-purpose variable gain amplifier, usable over a large range of supply voltages. It features an uncommitted preamplifier (preamp) with a usable gain range of 6 dB to 26 dB established by external resistors in the classical manner. The VGA gain range is 0 dB to 60 dB, and its absolute gain limits are -26 dB to +34 dB. When the preamplifier gain is adjusted for 12 dB, the combined 3 dB bandwidth of the preamp and VGA is 100 MHz, and the amplifier is fully usable to 80 MHz. With $\pm 5\text{ V}$ supplies, the maximum output swing is 7 V p-p.

Thanks to its X-Amp[®] architecture, excellent bandwidth uniformity is maintained across the entire gain range of the VGA. Intended for a broad spectrum of applications, the differential gain control interface provides precise linear-in-dB gain scaling of 50 dB/V over the temperature span of -55°C to $+125^{\circ}\text{C}$. The differential gain control is easy to interface with a variety of external circuits within the common-mode voltage limits of the AD8336.

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

06228-001

The large supply voltage range makes the AD8336 particularly suited for industrial medical applications and for video circuits. Dual-supply operation enables bipolar input signals, such as those generated by photodiodes or photomultiplier tubes.

The fully independent voltage feedback preamp allows both inverting and noninverting gain topologies, making it a fully bipolar VGA. The AD8336 can be used within the specified gain range of -14 dB to +60 dB by selecting a preamp gain between 6 dB and 26 dB and choosing appropriate feedback resistors. For the nominal preamp gain of 4 \times , the overall gain range is -14 dB to +46 dB.

In critical applications, the quiescent power can be reduced by about half by using the power adjust pin, PWRA. This is especially useful when operating with high supply voltages of up to $\pm 12\text{ V}$, or at high temperatures.

The operating temperature range is -55°C to $+125^{\circ}\text{C}$. The AD8336 is available in a 16-lead LFCSP (4 mm \times 4 mm).

¹ 4-layer JEDEC board, no airflow, exposed pad soldered to printed circuit board.

Stresses above those listed under the Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

- NOTES
1. NC = NO CONNECT.
 2. THE EXPOSED PAD IS NOT CONNECTED INTERNALLY. FOR INCREASED RELIABILITY OF THE SOLDER JOINTS AND MAXIMUM THERMAL CAPABILITY, IT IS RECOMMENDED THAT THE PADDLE BE SOLDERED TO THE GROUND PLANE.

THEORY OF OPERATION

OVERVIEW

The AD8336 is the first VGA designed for operation over exceptionally broad ranges of temperature and supply voltage. Its performance has been characterized from temperatures extending from -55°C to $+125^{\circ}\text{C}$, and supply voltages from $\pm 3\text{ V}$ to $\pm 12\text{ V}$. It is ideal for applications requiring dc coupling, large output voltage swings, very large gain ranges, extreme temperature variations, or a combination thereof.

The simplified block diagram is shown in Figure 77. The AD8336 includes a voltage feedback preamplifier, an amplifier with a fixed gain of 34 dB, a 60 dB attenuator, and various bias and interface circuitry. The independent voltage feedback op amp can be used in noninverting and inverting configurations and functions as a preamplifier to the variable gain amplifier (VGA). If desired, the op amp output (PRAO) and VGA input (VGAI) pins provide for connection of an interstage filter to eliminate noise and offset. The bandwidth of the AD8336 is dc to 100 MHz with a gain range of 60 dB (-14 dB to $+46\text{ dB}$).

For applications that require large supply voltages, a reduction in power is advantageous. The power reduction pin (PWRA) permits the power and bandwidth to be reduced by about half in such applications.

Figure 77. Simplified Block Diagram

To maintain low noise, the output stages of both the preamplifier and the VGA are capable of driving relatively small load resistances. However, at the largest supply voltages, the signal current may exceed safe operating limits for the amplifiers and, therefore, the load current must not exceed 50 mA. With a $\pm 12\text{ V}$ supply and $\pm 10\text{ V}$ output voltage at the preamplifier or VGA output, load resistances as low as $200\ \Omega$ are acceptable.

For power supply voltages $\geq \pm 10\text{ V}$, the maximum operating temperature range is derated to $+85^{\circ}\text{C}$ because the power may exceed safe limits (see the Absolute Maximum Ratings section).

Because harmonic distortion products may increase for various combinations of low impedance loads and high output voltage swings, it is recommended that the user determine load and drive conditions empirically.

PREAMPLIFIER

The gain of the uncommitted voltage feedback preamplifier is set with external resistors. The combined preamplifier and VGA gain is specified in two ranges: -14 dB to $+46\text{ dB}$ and 0 dB to 60 dB . Since the VGA gain is fixed at 34 dB ($50\times$), the preamp gain is adjusted for gains of 12 dB ($4\times$) and 26 dB ($200\times$).

With low preamplifier gains between $2\times$ and $4\times$, it may be desirable to reduce the high frequency gain with a shunt capacitor across R_{FB2} to ameliorate peaking in the frequency domain (see Figure 77). To maintain stability, the gain of the preamplifier must be 6 dB ($2\times$) or greater.

Typical of voltage feedback amplifier configurations, the gain-bandwidth product of the AD8336 is fixed (at 600); therefore, the bandwidth decreases as the gain is increased beyond the nominal gain value of $4\times$. For example, if the preamp gain is increased to $20\times$, the bandwidth reduces by a factor of 5 to about 20 MHz. The -3 dB bandwidth of the preamplifier with a gain of $4\times$ is about 150 MHz, and for the $20\times$ gain is about 30 MHz.

The preamp gain diminishes for an amplifier configured for inverting gain, using the same value of feedback resistors as for a noninverting amplifier, but the bandwidth remains unchanged. For example, if the noninverting gain is $4\times$, the inverting gain is $-3\times$, but the bandwidth stays the same as in the noninverting gain of $4\times$. However, because the output-referred noise of the preamplifier is the same in both cases, the input-referred noise increases as the ratio of the two gain values increases. For the previous example, the input-referred noise increases by a factor of $4/3$.

The output swing of the preamplifier is the same as for the VGA.

VGA

The architecture of the variable gain amplifier (VGA) section of the AD8336 is based on the Analog Devices, Inc., X-AMP (exponential amplifier), found in a wide variety of Analog Devices variable gain amplifiers. This type of VGA combines a ladder attenuator and interpolator, followed by a fixed-gain amplifier.

The gain control interface is fully differential, permitting positive or negative gain slopes. Note that the common-mode voltage of the gain control inputs increases with increasing supply.

The gain slope is 50 dB/V and the intercept is 16.4 dB when the nominal preamp gain is $4\times$ (12 dB). The intercept changes with the preamp gain; for example, when the preamp gain is set to $20\times$ (26 dB), the intercept becomes 30.4 dB .

Pin VGAI is connected to the input of the ladder attenuator. The ladder ratio is $R/2R$ and the nominal resistance is $320\ \Omega$. To reduce preamp loading and large-signal dissipation, the input resistance at Pin VGAI is $1.28\text{ k}\Omega$. Safe current density and power dissipation levels are maintained even when large dc signals are applied to the ladder.

The tap resistance of the resistors within the $R/2R$ ladder is $640\ \Omega/3$, or $213.3\ \Omega$, and is the Johnson noise source of the attenuator.

SETTING THE GAIN

The overall gain of the AD8336 is the sum (in decibels) or the product (magnitude) of the preamp gain and the VGA gain. The preamp gain is calculated as with any op amp, as seen in the Applications Information section. It is most convenient to think of the device gain in exponential terms (that is, in decibels) since the VGA responds linearly in decibels with changes in control voltage V_{GAIN} at the gain pins.

The gain equation for the VGA is

$$\text{VGA Gain (dB)} = \left[V_{GAIN}(\text{V}) \times \frac{50 \text{ dB}}{\text{V}} \right] + 4.4 \text{ dB}$$

where $V_{GAIN} = V_{GPOS} - V_{GNEG}$.

The gain and gain range of the VGA are both fixed at 34 dB and 60 dB, respectively; thus, the composite device gain is changed by adjusting the preamp gain. For a preamp gain of 12 dB ($4\times$), the composite gain is -14 dB to $+46$ dB. Therefore, the calculation for the composite gain (in decibels) is

$$\text{Composite Gain} = G_{PRA} + [V_{GAIN}(\text{V}) \times 49.9 \text{ dB/V}] + 4.4 \text{ dB}$$

For example, the midpoint gain when the preamp gain is 12 dB is

$$12 \text{ dB} + [0 \text{ V} \times 49.9 \text{ dB/V}] + 4.4 \text{ dB} = 16.4 \text{ dB}$$

Figure 3 is a plot of gain in decibels vs. V_{GAIN} in millivolts, when the preamp gain is 12 dB ($4\times$). Note that the computed result closely matches the plot of actual gain.

In Figure 3, the gain slope flattens at the limits of the V_{GAIN} input. The gain response is linear-in-dB over the center 80% of the control range of the device. Figure 78 shows the ideal gain characteristics for the VGA stage gain, the composite gain, and the preamp gain.

Figure 78. Ideal Gain Characteristics of the AD8336

NOISE

The noise of the AD8336 is dependent on the value of the VGA gain. At maximum V_{GAIN} , the dominant noise source is the preamp, but it shifts to the VGA as V_{GAIN} diminishes.

The input-referred noise at the highest VGA gain and a preamp gain of $4\times$, with $R_{FB1} = 100 \Omega$ and $R_{FB2} = 301 \Omega$, is $3 \text{ nV}/\sqrt{\text{Hz}}$ and is determined by the preamp and its gain setting resistors. See Table 4 for the noise components for the preamp.

Table 4. AD8336 Noise Components for Preamp Gain = $4\times$

Noise Component	Noise Voltage ($\text{nV}/\sqrt{\text{Hz}}$)
Op Amp (Gain = $4\times$)	2.6
$R_{FB1} = 100 \Omega$	0.96
$R_{FB2} = 301 \Omega$	0.55
VGA	0.77

Using the values listed in Table 4, the total noise of the AD8336 is slightly less than $3 \text{ nV}/\sqrt{\text{Hz}}$, referred to the input. Although the input noise referred to the VGA is $3.1 \text{ nV}/\sqrt{\text{Hz}}$, the input-referred noise at the preamp is $0.77 \text{ nV}/\sqrt{\text{Hz}}$ when divided by the preamplifier gain of $4\times$.

At other than maximum gain, the noise of the VGA is determined from the output noise. The noise in the center of the gain range is about $150 \text{ nV}/\sqrt{\text{Hz}}$. Because the gain of the fixed-gain amplifier that is part of the VGA is $50\times$, the VGA input-referred noise is approximately $3 \text{ nV}/\sqrt{\text{Hz}}$, the same value as the preamp and VGA combined. This is expected since the input-referred noise is the same at the input of the attenuator at maximum gain. However, the noise referred to the VGAI pin (the preamp output) increases by the amount of attenuation through the ladder network. The noise at any point along the ladder network is primarily composed of the ladder resistance noise, the noise of the input devices, and the feedback resistor network noise. The ladder network and the input devices are the largest noise sources.

At minimum gain, the output noise increases slightly to about $180 \text{ nV}/\sqrt{\text{Hz}}$ because of the finite structure of the X-AMP.

OFFSET VOLTAGE

Extensive cancellation circuitry included in the variable gain amplifier section minimizes locally generated offset voltages. However, when operated at very large values of gain, dc voltage errors at the output can still result from small dc input voltages. When configured for the nominal gain range of -14 dB to $+46$ dB, the maximum gain is $200\times$ and an offset of only $100 \mu\text{V}$ at the input generates 20 mV at the output.

The primary source for dc offset errors is the preamplifier; ac coupling between the PRAO and VGAI pins is the simplest solution. In applications where dc coupling is essential, a compensating current can be injected at the INPN input (Pin 5) to cancel preamp offset. The direction of the compensating current depends on the polarity of the offset voltage.

APPLICATIONS INFORMATION

AMPLIFIER CONFIGURATION

The AD8336 amplifiers can be configured in various options. In addition to the 60 dB gain range variable gain stage, an uncommitted voltage gain amplifier is available to the user as a preamplifier. The preamplifier connections are separate to enable noninverting or inverting gain configurations or the use of interstage filtering. The AD8336 can be used as a cascade connected VGA with preamp input, as a standalone VGA, or as a standalone preamplifier. This section describes some of the possible applications.

Figure 79. Application Block Diagram

PREAMPLIFIER

While observing just a few constraints, the uncommitted voltage feedback preamplifier of the AD8336 can be connected in a variety of standard high frequency op amp configurations. The amplifier is optimized for a gain of 4× (12 dB) and has a gain bandwidth product of 600 MHz. At a gain of 4×, the bandwidth is 150 MHz. The preamplifier gain can be adjusted to a minimum gain of 2×; however, there will be a small peak in the response at high frequencies. At higher preamplifier gains, the bandwidth diminishes proportionally in conformance to the classical voltage gain amplifier GBW relationship.

While setting the overall gain of the AD8336, the user needs to consider the input-referred offset voltage of the preamplifier. Although the offset of the attenuator and postamplifier are almost negligible, the preamplifier offset voltage, if uncorrected, is increased by the combined gain of the preamplifier and post-amplifier. Therefore, for a maximum gain of 60 dB, an input offset voltage of only 200 μV results in an error of 200 mV at the output.

Circuit Configuration for Noninverting Gain

The noninverting configuration is shown in Figure 80. The preamp gain is described by the classical op amp gain equation:

$$Gain = \frac{R_{FB2}}{R_{FB1}} + 1$$

The practical gain limits for this amplifier are 6 dB to 26 dB. The gain bandwidth product is about 600 MHz, so at 150 MHz, the maximum achievable gain is 12 dB (4×). The minimum gain is established internally by fixed loop compensation and is 6 dB (2×). This amplifier is not designed for unity-gain operation. Table 5 shows the gain and bandwidth for the noninverting gain configuration.

Figure 80. Circuit Configuration for Noninverting Gain

The preamplifier output reliably sources and sinks currents up to 50 mA. When using ±5 V power supplies, the suggested sum of the output resistor values is 400 Ω total for the optimal trade-off between distortion and noise. Much of the low gain value device characterization was performed with resistor values of 301 Ω and 100 Ω, resulting in a preamplifier gain of 12 dB (4×). With supply voltages between ±5 V and ±12 V, the sum of the output resistance should be increased accordingly; a total resistance of 1 kΩ is recommended. Larger resistance values, subject to a trade-off in higher noise performance, can be used if circuit power and load driving is an issue. When considering the total power dissipation, remember that the input ladder resistance of the VGA is part of the preamp load.

Table 5. Gain and Bandwidth for Noninverting Preamplifier Configuration

Preamp Gain		Preamp BW (MHz)	Composite Gain (dB)
Numerical	dB		
4×	12	150	-14 to +46
8×	18	60	-8 to +52
16×	24	30	-2 to +58
20×	26	25	0 to +60

Circuit Configuration for Inverting Gain

The preamplifier can also be used in an inverting configuration, as shown in Figure 81.

Figure 81. Circuit Configuration for Inverting Gain

The considerations regarding total resistance vs. distortion, noise, and power that were noted in the noninverting case also apply in the inverting case, except that the amplifier can be operated at unity inverting gain. The signal gain is reduced while the noise gain is the same as for the noninverting configuration:

$$\text{Signal Gain} = \frac{R_{FB2}}{R_{FB1}}$$

and

$$\text{Noise Gain} = \frac{R_{FB2}}{R_{FB1}} + 1$$

USING THE POWER ADJUST FEATURE

The AD8336 has the provision to operate at lower power with a trade-off in bandwidth. The power reduction applies to the preamp and the VGA sections, and the bandwidth is reduced equally between them. Reducing the power is particularly useful when operating with higher supply voltages and lower values of output loading that would otherwise stress the output amplifiers. When Pin PWRA is grounded, the amplifiers operate in their default mode, and the combined 3 dB bandwidth is 80 MHz with the preamp gain adjusted to 4×. When the voltage on Pin PWRA is between 1.2 V and 5 V, the power is reduced by approximately half and the 3 dB bandwidth reduces to approximately 35 MHz. The voltage at Pin PWRA must not exceed 5 V.

DRIVING CAPACITIVE LOADS

The output stages of the AD8336 are stable with capacitive loads up to 47 pF for a supply voltage of ±3 V and with capacitive loads up to 10 pF for supply voltages up to ±8 V. For larger combined values of load capacitance and/or supply voltage, a 20 Ω series resistor is recommended for stability.

The influence of capacitance and supply voltage are shown in Figure 50 and Figure 51, where representative combinations of load capacitance and supply voltage requiring a 20 Ω resistor are marked with an asterisk. No resistor is required for the ±3 V plots in Figure 49, but a resistor is required for most of the ±12 V plots in Figure 51.

EVALUATION BOARD

An evaluation board, AD8336-EVALZ, is available online for the AD8336. Figure 82 is a photo of the board.

The board is shipped from the factory configured for a non-inverting preamp gain of 4×. To change the value of the gain of the preamp or to change the gain polarity to inverting, alter the component values or install components in the alternate locations provided. All components are standard 0603 size, and the board is compliant with RoHS requirements. Table 6 shows the components to be removed and added to change the amplifier configuration to inverting gain.

Table 6. Component Changes for Inverting Configuration

Remove	Install
R4, R7	R5, R6

OPTIONAL CIRCUITRY

The AD8336 features differential inputs for the gain control, permitting nonzero or floating gain control inputs. To avoid any delay in making the board operational, the gain input circuit is shipped with Pin GNEG connected to ground via a 0 Ω resistor in the R17 location. The user can adjust the gain of the device by driving the GPOS test loop with a power supply or voltage reference. Optional resistor networks R15/R17 and R13/R14 provide fixed-gain bias voltages at Pin GNEG and Pin GPOS for non-zero common-mode voltages. The gain control can also be driven with an active input such as a ramp. Provision is made for an optional SMA connector at PRVG for monitoring the preamp output or for driving the VGA from an external source. Remove the 0 Ω resistor at R9 to isolate the preamp from an external generator. The capacitor at Location C1 limits the bandwidth of the preamplifier.

BOARD LAYOUT CONSIDERATIONS

The evaluation board uses four layers, with power and ground planes located between two conductor layers. This arrangement is highly recommended for customers, and several views of the board are provided as reference for board layout details. When laying out a printed circuit board for the AD8336, remember to provide a pad beneath the device to solder the exposed pad of the matching device. The pad in the board should have at least five vias to provide a thermal path for the chip scale package. Unlike leaded devices, the thermal pad is the primary means to remove heat dissipated within the device.

NOTES

Стандарт Электрон Связь

Мы молодая и активно развивающаяся компания в области поставок электронных компонентов. Мы поставляем электронные компоненты отечественного и импортного производства напрямую от производителей и с крупнейших складов мира.

Благодаря сотрудничеству с мировыми поставщиками мы осуществляем комплексные и плановые поставки широчайшего спектра электронных компонентов.

Собственная эффективная логистика и склад в обеспечивает надежную поставку продукции в точно указанные сроки по всей России.

Мы осуществляем техническую поддержку нашим клиентам и предпродажную проверку качества продукции. На все поставляемые продукты мы предоставляем гарантию .

Осуществляем поставки продукции под контролем ВП МО РФ на предприятия военно-промышленного комплекса России , а также работаем в рамках 275 ФЗ с открытием отдельных счетов в уполномоченном банке. Система менеджмента качества компании соответствует требованиям ГОСТ ISO 9001.

Минимальные сроки поставки, гибкие цены, неограниченный ассортимент и индивидуальный подход к клиентам являются основой для выстраивания долгосрочного и эффективного сотрудничества с предприятиями радиоэлектронной промышленности, предприятиями ВПК и научно-исследовательскими институтами России.

С нами вы становитесь еще успешнее!
