## Data Sheet

## Description

Avago Technologies' ATF-55143 is a high dynamic range, very low noise, single supply E-PHEMT housed in a 4-lead SC-70 (SOT-343) surface mount plastic package.
The combination of high gain, high linearity and low noise makes the ATF-55143 ideal for cellular/PCS handsets, wireless data systems (WLL/RLL, WLAN and MMDS) and other systems in the 450 MHz to 6 GHz frequency range.

## Surface Mount Package SOT-343

## Pin Connections and Package Marking

Note:
Top View. Package marking provides orientation and identification
"5F" = Device Code
" $x$ " = Date code character identifies month of manufacture.

Attention: Observe precautions for handling electrostatic sensitive devices. ESD Machine Model (Class A)
ESD Human Body Model (Class 0)
Refer to Avago Application Note A004R:
Electrostatic Discharge Damage and Control.

## Features

- High linearity performance
- Single Supply Enhancement Mode Technology ${ }^{[1]}$
- Very low noise figure
- Excellent uniformity in product specifications
- 400 micron gate width
- Low cost surface mount small plastic package SOT343 (4 lead SC-70)
- Tape-and-Reel packaging option available
- Lead Free Option Available

## Specifications

- 2 GHz; 2.7V, 10 mA (Typ.)
- 24.2 dBm output $3^{\text {rd }}$ order intercept
- 14.4 dBm output power at 1 dB gain compression
- 0.6 dB noise figure
- 17.7 dB associated gain
- Lead-free option available

## Applications

- Low noise amplifier for cellular/PCS handsets
- LNA for WLAN, WLL/RLL and MMDS applications
- General purpose discrete E-PHEMT for other ultra low noise applications

## Note:

1. Enhancement mode technology requires positive Vgs, thereby eliminating the need for the negative gate voltage associated with conventional depletion mode devices.

Figure 14. IIP3 vs. $\mathrm{I}_{\mathrm{ds}}$ and $\mathrm{V}_{\mathrm{ds}}$ at $\mathbf{2} \mathbf{~ G H z .}{ }^{[1]}$

Notes:

1. Measurements at 2 GHz were made on a fixed tuned production test board that was tuned for optimal OIP3 match with reasonable noise figure at $2.7 \mathrm{~V}, 10 \mathrm{~mA}$ bias. This circuit represents a trade-off between optimal noise match, maximum OIP3 match and a realizable match based on production test board requirements. Measurements taken above and below 2 GHz were made using a double stub tuner at the input tuned for low noise and a double stub tuner at the output tuned for maximum OIP3. Circuit losses have been de-embedded from actual measurements.
2. P 1 dB measurements are performed with passive biasing. Quiescent drain current, $I_{\mathrm{dsq}}$ is set with zero RF drive applied. As P1dB is approached, the drain current may increase or decrease depending on frequency and dc bias point. At lower values of $I_{d s q^{\prime}}$ the device is running close to class $B$ as power output approaches P 1 dB . This results in higher P 1 dB and higher PAE (power added efficiency) when compared to a device that is driven by a constant current source as is typically done with active biasing. As an example, at a $V_{D S}=2.7 \mathrm{~V}$ and $I_{d s q}=5 \mathrm{~mA}$, $I_{d}$ increases to 15 mA as a P 1 dB of +14.5 dBm is approached.

Figure 26. MSG/MAG and $\left|\mathrm{S}_{21}\right|^{2}$ vs. Frequency at $2 \mathrm{~V}, 10 \mathrm{~mA}$.

Notes:

1. $F_{\text {min }}$ values at 2 GHz and higher are based on measurements while the $F_{\text {mins }}$ below 2 GHz have been extrapolated. The $F_{\text {min }}$ values are based on a set of 16 noise figure measurements made at 16 different impedances using an ATN NP5 test system. From these measurements $\mathrm{F}_{\text {min }}$ is calculated. Refer to the noise parameter application section for more information.
2. $S$ and noise parameters are measured on a microstrip line made on 0.025 inch thick alumina carrier. The input reference plane is at the end of the gate lead. The output reference plane is at the end of the drain lead. The parameters include the effect of four plated through via holes connecting source landing pads on top of the test carrier to the microstrip ground plane on the bottom side of the carrier. Two 0.020 inch diameter via holes are placed within 0.010 inch from each source lead contact point, one via on each side of that point.

Figure 27. MSG/MAG and $\left|\mathrm{S}_{21}\right|^{2}$ vs. Frequency at $2 \mathrm{~V}, 15 \mathrm{~mA}$.

Notes:

1. $F_{\text {min }}$ values at 2 GHz and higher are based on measurements while the $F_{\text {mins }}$ below 2 GHz have been extrapolated. The $F_{\text {min }}$ values are based on a set of 16 noise figure measurements made at 16 different impedances using an ATN NP5 test system. From these measurements a true $F_{\text {min }}$ is calculated. Refer to the noise parameter application section for more information.
2. $S$ and noise parameters are measured on a microstrip line made on 0.025 inch thick alumina carrier. The input reference plane is at the end of the gate lead. The output reference plane is at the end of the drain lead. The parameters include the effect of four plated through via holes connecting source landing pads on top of the test carrier to the microstrip ground plane on the bottom side of the carrier. Two 0.020 inch diameter via holes are placed within 0.010 inch from each source lead contact point, one via on each side of that point.

Notes:

1. $F_{\text {min }}$ values at 2 GHz and higher are based on measurements while the $F_{\text {mins }}$ below 2 GHz have been extrapolated. The $F_{\text {min }}$ values are based on a set of 16 noise figure measurements made at 16 different impedances using an ATN NP5 test system. From these measurements a true $F_{\text {min }}$ is calculated. Refer to the noise parameter application section for more information.
2. $S$ and noise parameters are measured on a microstrip line made on 0.025 inch thick alumina carrier. The input reference plane is at the end of the gate lead. The output reference plane is at the end of the drain lead. The parameters include the effect of four plated through via holes connecting source landing pads on top of the test carrier to the microstrip ground plane on the bottom side of the carrier. Two 0.020 inch diameter via holes are placed within 0.010 inch from each source lead contact point, one via on each side of that point.

Figure 32. MSG/MAG and $\left|\mathrm{S}_{21}\right|^{2}$ vs. Frequency at $3 \mathrm{~V}, \mathbf{3 0} \mathrm{~mA}$.

Notes:

1. $F_{\text {min }}$ values at 2 GHz and higher are based on measurements while the $F_{\text {mins }}$ below 2 GHz have been extrapolated. The $F_{\text {min }}$ values are based on a set of 16 noise figure measurements made at 16 different impedances using an ATN NP5 test system. From these measurements a true $F_{\text {min }}$ is calculated. Refer to the noise parameter application section for more information.
2. $S$ and noise parameters are measured on a microstrip line made on 0.025 inch thick alumina carrier. The input reference plane is at the end of the gate lead. The output reference plane is at the end of the drain lead. The parameters include the effect of four plated through via holes connecting source landing pads on top of the test carrier to the microstrip ground plane on the bottom side of the carrier. Two 0.020 inch diameter via holes are placed within 0.010 inch from each source lead contact point, one via on each side of that point.

## ATF-55143 Applications Information

## Introduction

Avago Technologies' ATF-55143 is a low noise enhancement mode PHEMT designed for use in low cost commercial applications in the VHF through 6 GHz frequency range. As opposed to a typical depletion mode PHEMT where the gate must be made negative with respect to the source for proper operation, an enhancement mode PHEMT requires that the gate be made more positive than the source for normal operation. Therefore a negative power supply voltage is not required for an enhancement mode device. Biasing an enhancement mode PHEMT is much like biasing the typical bipolar junction transistor. Instead of a 0.7 V base to emitter voltage, the ATF-55143 enhancement mode PHEMT requires about a 0.47 V potential between the gate and source for a nominal drain current of 10 mA .

## Matching Networks

The techniques for impedance matching an enhancement mode device are very similar to those for matching a depletion mode device. The only difference is in the method of supplying gate bias. S and Noise Parameters for various bias conditions are listed in this data sheet. The circuit shown in Figure 33 shows a typical LNA circuit normally used for 900 and 1900 MHz applications (Consult the Avago Technologies website for application notes covering specific applications). High pass impedance matching networks consisting of L1/C1 and L4/C4 provide the appropriate match for noise figure, gain, S11 and S22. The high pass structure also provides low frequency gain reduction which can be beneficial from the standpoint of improving out-of-band rejection.

Figure 33. Typical ATF-55143 LNA with Passive Biasing.

Capacitors C2 and C5 provide a low impedance in-band RF bypass for the matching networks. Resistors R3 and R4 provide a very important low frequency termination for the device. The resistive termination improves low frequency stability. Capacitors C3 and C6 provide the low frequency RF bypass for resistors R3 and R4. Their value should be chosen carefully as C3 and C6 also provide a termination for low frequency mixing products. These mixing products are as a result of two or more in-
band signals mixing and producing third order in-band distortion products. The low frequency or difference mixing products are terminated by C3 and C6. For best suppression of third order distortion products based on the CDMA 1.25 MHz signal spacing, C3 and C6 should be $0.1 \mu \mathrm{~F}$ in value. Smaller values of capacitance will not suppress the generation of the 1.25 MHz difference signal and as a result will show up as poorer two tone IP3 results.

## Bias Networks

One of the major advantages of the enhancement mode technology is that it allows the designer to be able to dc ground the source leads and then merely apply a positive voltage on the gate to set the desired amount of quiescent drain current $\mathrm{I}_{\mathrm{d}}$.

Whereas a depletion mode PHEMT pulls maximum drain current when $\mathrm{V}_{\mathrm{gs}}=0 \mathrm{~V}$, an enhancement mode PHEMT pulls only a small amount of leakage current when $\mathrm{V}_{\mathrm{gs}}=0 \mathrm{~V}$. Only when $\mathrm{V}_{\mathrm{gs}}$ is increased above $\mathrm{V}_{\mathrm{th}}$, the device threshold voltage, will drain current start to flow. At a $\mathrm{V}_{\mathrm{ds}}$ of 2.7 V and a nominal $\mathrm{V}_{\mathrm{gs}}$ of 0.47 V , the drain current $I_{d}$ will be approximately 10 mA . The data sheet suggests a minimum and maximum $\mathrm{V}_{\mathrm{gs}}$ over which the desired amount of drain current will be achieved. It is also important to note that if the gate terminal is left open circuited, the device will pull some amount of drain current due to leakage current creating a voltage differential between the gate and source terminals.

## Passive Biasing

Passive biasing of the ATF-55143 is accomplished by the use of a voltage divider consisting of R1 and R2. The voltage for the divider is derived from the drain voltage which provides a form of voltage feedback through the use of R3 to help keep drain current constant. Resistor R5 (approximately $10 \mathrm{k} \Omega$ ) is added to limit the gate current of enhancement mode devices such as the ATF-55143. This is especially important when the device is driven to $P_{1 d B}$ or $P_{S A T}$.

Resistor R3 is calculated based on desired $\mathrm{V}_{\mathrm{ds}} \mathrm{I}_{\mathrm{ds}}$ and available power supply voltage.
$R 3=\frac{V_{D D}-V_{d s}}{I_{d s}+I_{B B}}$
$V_{D D}$ is the power supply voltage.
$V_{d s}$ is the device drain to source voltage.
$I_{d s}$ is the desired drain current.
$I_{B B}$ is the current flowing through the R1/R2 resistor voltage divider network.

The values of resistors R1 and R2 are calculated with the following formulas
$\mathrm{R} 1=\frac{\mathrm{V}_{\mathrm{gs}}}{\mathrm{I}_{\mathrm{BB}}}$
$R 2=\frac{\left(V_{\mathrm{ds}}-\mathrm{V}_{\mathrm{gs}}\right) \mathrm{R} 1}{\mathrm{~V}_{\mathrm{gs}}}$

Example Circuit
$\mathrm{V}_{\mathrm{DD}}=3 \mathrm{~V}$
$\mathrm{V}_{\mathrm{ds}}=2.7 \mathrm{~V}$
$I_{d s}=10 \mathrm{~mA}$
$V_{\mathrm{gs}}^{\mathrm{ds}}=0.47 \mathrm{~V}$
Choose $I_{B B}$ to be at least 10X the normal expected gate leakage current. $I_{B B}$ was conservatively chosen to be 0.5 mA for this example. Using equations (1), (2), and (3) the resistors are calculated as follows
$R 1=940 \Omega$
$R 2=4460 \Omega$
$R 3=28.6 \Omega$

## Active Biasing

Active biasing provides a means of keeping the quiescent bias point constant over temperature and constant over lot to lot variations in device dc performance. The advantage of the active biasing of an enhancement mode PHEMT versus a depletion mode PHEMT is that a negative power source is not required. The techniques of active biasing an enhancement mode device are very similar to those used to bias a bipolar junction transistor.

Figure 34. Typical ATF-55143 LNA with Active Biasing.

An active bias scheme is shown in Figure 34. R1 and R2 provide a constant voltage source at the base of a PNP transistor at Q2. The constant voltage at the base of Q2 is raised by 0.7 volts at the emitter. The constant emitter voltage plus the regulated $\mathrm{V}_{\mathrm{DD}}$ supply are present across resistor R3. Constant voltage across R3 provides a constant current supply for the drain current. Resistors R1 and R2 are used to set the desired Vds. The combined
series value of these resistors also sets the amount of extra current consumed by the bias network. The equations that describe the circuit's operation are as follows.
$V_{E}=V_{d s}+\left(I_{d s} \cdot R 4\right)$
$R 3=\frac{V_{D D}-V_{E}}{I_{d s}}$
$V_{B}=V_{E}-V_{B E}$
$V_{B}=\frac{R 1}{R 1+R 2} V_{D D}$
$V_{D D}=I_{B B}(R 1+R 2)$
Rearranging equation (4) provides the following formula
$R 2=\frac{R_{1}\left(V_{D D}-V_{B}\right)}{V_{B}}$
and rearranging equation (5) provides the following formula

$$
\begin{equation*}
R 1=\frac{V_{D D}}{I_{B B}\left(1+\frac{V_{D D}-V_{B}}{V_{B}}\right)} \tag{5A}
\end{equation*}
$$

Example Circuit
$V_{D D}=3 V \quad I_{B B}=0.5 \mathrm{~mA}$
$\mathrm{V}_{\mathrm{ds}}=2.7 \mathrm{~V}$
$\mathrm{I}_{\mathrm{ds}}=10 \mathrm{~mA}$
$R 4=10 \Omega$
$\mathrm{V}_{\mathrm{BE}}=0.7 \mathrm{~V}$
Equation (1) calculates the required voltage at the emitter of the PNP transistor based on desired $\mathrm{V}_{\mathrm{ds}}$ and $\mathrm{I}_{\mathrm{ds}}$ through resistor R4 to be 2.8 V . Equation (2) calculates the value of resistor R3 which determines the drain current $I_{d s}$. In the example $\mathrm{R} 3=20 \Omega$. Equation (3) calculates the voltage required at the junction of resistors R1 and R2. This voltage plus the step-up of the base emitter junction determines the regulated $\mathrm{V}_{\mathrm{ds}}$. Equations (4) and (5) are solved simultaneously to determine the value of resistors R1 and R2. In the example R1 $=4200 \Omega$ and $R 2=1800 \Omega$. R 7 is chosen to be $1 \mathrm{k} \Omega$. This resistor keeps a small amount of current flowing through Q2 to help maintain bias stability. R6 is chosen to be $10 \mathrm{k} \Omega$. This value of resistance is necessary to limit Q1 gate current in the presence of high RF drive levels (especially when Q1 is driven to the $P_{1 d B}$ gain compression point). C7 provides a low frequency bypass to keep noise from Q2 effecting the operation of Q1. C7 is typically $0.1 \mu \mathrm{~F}$.

## ATF-55143 ADS Package Model

## Designing with S and Noise Parameters and the Non-Linear Model

The non-linear model describing the ATF-55143 includes both the die and associated package model. The package model includes the effect of the pins but does not include the effect of the additional source inductance associated with grounding the source leads through the printed circuit board. The device $S$ and Noise Parameters do include the effect of 0.020 inch thickness printed circuit board vias. When comparing simulation results between the measured $S$ parameters and the simulated non-linear model, be sure to include the effect of the printed circuit board to get an accurate comparison. This is shown schematically in Figure 35.

## For Further Information

The information presented here is an introduction to the use of the ATF-55143 enhancement mode PHEMT. More detailed application circuit information is available from Avago Technologies. Consult the web page or your local Avago Technologies sales representative.

## Noise Parameter Applications Information

$F_{\text {min }}$ values at 2 GHz and higher are based on measurements while the $F_{\text {mins }}$ below 2 GHz have been extrapolated. The $F_{\text {min }}$ values are based on a set of 16 noise figure measurements made at 16 different impedances using an ATN NP5 test system. From these measurements, a true $F_{\text {min }}$ is calculated. $F_{\text {min }}$ represents the true minimum noise figure of the device when the device is presented with an impedance matching network that transforms the source impedance, typically $50 \Omega$, to an impedance represented by the reflection coefficient $\Gamma_{\text {。 }}$. The designer must design a matching network that will present $\Gamma_{o}$ to the device with minimal associated circuit losses. The noise figure of the completed amplifier is equal to the noise figure of the device plus the losses of the matching network preceding the device. The noise figure of the device is equal to $\mathrm{F}_{\text {min }}$ only when the device is presented with $\Gamma_{0}$. If the reflection coefficient of the matching network is other than $\Gamma_{o^{\prime}}$ then the noise figure of the device will be greater than $F_{\text {min }}$ based on the following equation.
$N F=F_{\text {min }}+\frac{4 R_{n}}{Z o} \frac{\left|\Gamma_{s}-\Gamma_{o}\right|^{2}}{\left(\left|1+\Gamma_{o}\right|^{2}\right)\left(1-\mid \Gamma_{s}{ }^{2}\right)}$

Where $R_{n} / Z_{o}$ is the normalized noise resistance, $\Gamma_{o}$ is the optimum reflection coefficient required to produce $F_{\min }$ and $\Gamma_{s}$ is the reflection coefficient of the source impedance actually presented to the device. The losses of the matching networks are non-zero and they will also add to the noise figure of the device creating a higher amplifier noise figure. The losses of the matching networks are related to the Q of the components and associated printed circuit board loss. $\Gamma_{0}$ is typically fairly low at higher frequencies and increases as frequency is lowered. Larger gate width devices will typically have a lower $\Gamma_{o}$ as compared to narrower gate width devices.

Typically for FETs, the higher $\Gamma_{o}$ usually infers that an impedance much higher than $50 \Omega$ is required for the device to produce $F_{\text {min }}$. At VHF frequencies and even lower L Band frequencies, the required impedance can be in the vicinity of several thousand ohms. Matching to such a high impedance requires very hi-Q components in order to minimize circuit losses. As an example at 900 MHz , when airwound coils $(\mathrm{Q}>100)$ are used for matching networks, the loss can still be up to 0.25 dB which will add directly to the noise figure of the device. Using multilayer molded inductors with Qs in the 30 to 50 range results in additional loss over the airwound coil. Losses as high as 0.5 dB or greater add to the typi$\mathrm{cal} 0.15 \mathrm{~dB} \mathrm{~F}_{\text {min }}$ of the device creating an amplifier noise figure of nearly 0.65 dB . A discussion concerning calculated and measured circuit losses and their effect on amplifier noise figure is covered in Avago Technologies Application 1085.

## Стандарт Злектрон Связь

Мы молодая и активно развивающаяся компания в области поставок электронных компонентов. Мы поставляем электронные компоненты отечественного и импортного производства напрямую от производителей и с крупнейших складов мира.

Благодаря сотрудничеству с мировыми поставщиками мы осуществляем комплексные и плановые поставки широчайшего спектра электронных компонентов.

Собственная эффективная логистика и склад в обеспечивает надежную поставку продукции в точно указанные сроки по всей России.

Мы осуществляем техническую поддержку нашим клиентам и предпродажную проверку качества продукции. На все поставляемые продукты мы предоставляем гарантию.

Осуществляем поставки продукции под контролем ВП МО РФ на предприятия военно-промышленного комплекса России, а также работаем в рамках 275 ФЗ с открытием отдельных счетов в уполномоченном банке. Система менеджмента качества компании соответствует требованиям ГОСТ ISO 9001.

Минимальные сроки поставки, гибкие цены, неограниченный ассортимент и индивидуальный подход к клиентам являются основой для выстраивания долгосрочного и эффективного сотрудничества с предприятиями радиоэлектронной промышленности, предприятиями ВПК и научноисследовательскими институтами России.

С нами вы становитесь еще успешнее!
