Notes:

- 1) To prevent input signal oscillations minimize wiring length to controller (~2cm). Additional RC filtering (C₅ etc.) may be required. If filtering is added be careful to maintain proper dead time and voltage levels. See application notes for details.
- 2) Internal HVIC provides high voltage level shifting allowing direct connection of all six driving signals to the controller.
- 3) F_O output is an open collector type. Pull up resistor (R₃) should be adjusted to current sink capability of the controller.
- 4) Use only one V_{NC} Pin (either 9 or 16) and leave the other open.
- 5) Boot strap supply component values must be adjusted depending on the PWM frequency and technique.
- 6) Wiring length associated with R_{SHUNT}, R_{SF}, C_{SF} must be minimized to avoid improper operation of the OC function.
- 7) R_{SF}, C_{SF} set over current protection trip time. Recommend time constant is 1.5μs-2.0μs. See application notes.
- 8) Local decoupling/high frequency filter capacitors must be connected as close as possible to the modules pins.
- 9) The length of the DC link wiring between C₅, C₆, the DIP's P terminal and the shunt must be minimized to prevent excessive transient voltages. In particular C₆ should be mounted as close to the DIP as possible.
- 10) Use high quality, tight tolerance current sensing resistor. Connect resistor as close as possible to the DIP's N terminal. Be careful to check for proper power rating. See application notes for calculation of resistance value.

- B1: Control supply voltage rise – After the voltage level reaches UV_{Dr} , the drive circuit begins to work at the rising edge of the next input signal.
- B2: Normal operation – IGBT turn on and conducting current.
- B3: Under-voltage trip (UV_{Dt}).
- B4: IGBT turn off regardless of the control input level.
- B5: F_O output during under-voltage period, however, the minimum pulse width is $20\mu s$.

Under-Voltage Protection (Upper-side, UV_{DB})

- C1: Control supply voltage rises – After the voltage level reaches UV_{DBr} , the drive circuit begins to work at the rising edge of the next input signal.
- C2: Normal operation – IGBT turn on and conducting current.
- C3: Under-voltage trip (UV_{DBt}).
- C4: IGBT stays off regardless of the control input level, but there is no F_O signal output.
- C5: Under-voltage reset (UV_{Dr}).
- C6: Normal operation – IGBT turn on and conducting current.

Typical Interface Circuit

NOTE: RC coupling at each input (parts shown dotted) may change depending on the PWM control scheme used in the application and the wiring impedance of the printed circuit board. The DIP-IPM input signal section integrates a 3.3kΩ (min) pull-down resistor. Therefore, when using an external filtering resistor, care must be taken to satisfy the turn-on threshold voltage requirement.
